Consequently, in the top panel of Figure 3, based on Model C, we present revised fitted logit-hazard functions describing the risks of first divorce among prototypical participants who possessed a college degree at first marriage (dashed line) versus those who did not (solid line). In contrast with the fitted functions obtained from Model B, in Figure 2, there are now differences from time interval to interval in the impact of predictor *DEGREE*. In the first two discrete-time periods, for instance, after years 4 and 8, differences in logit-hazard between the two groups are small. Between 8 and 24 years, logit-hazard values describing the risks of divorce for those with degrees at marriage then drop more rapidly, representing a declining lower risk of a first divorce for these folk. During period 7 (28 years into marriage), the pattern of risk reverses and folk who entered the marriage with a college degree now have a higher logit-hazard of first divorce. By year 40, the pattern has flipped back, and logit-risk for the college-educated folk has become lower again. Overall, although they enjoy lower risks of divorce in most time periods, it seems as though the peaks in risk now arrive somewhat earlier for participants who entered their marriages with degrees, compared to those that did not.

To better understand differences in risk of divorce over time for folk who entered their marriages with, and without, college degrees, we have plotted fitted hazard and survivor functions

Figure 3 Fitted logit-hazard, hazard, and survivor functions displaying the risk of a first divorce, in Wisconsin, as a function of first-marriage duration (in discrete periods of 4 years) for prototypical participants who had attained a bachelor's degree prior to entering into marriage (dashed profile) and did not (solid profile) (from fitted Model C, containing the two-way interaction between *DEGREE* and a general specification of time, in Table 4).

computed from Model C, in the middle and bottom panels of Figure 3. The estimated (hazard) probability of a first divorce for prototypical holders of college degrees at marriage is largest in the second time period. Almost 3% of participants who were married at least 4 years were divorced by the end of 8 years of marriage. At this point, the hazard probability for the no-degree group is only slightly larger (0.034). However, after the second time period, the risk of a first divorce plummets for the group with degrees, while continuing to rise for the no-degree group. These latter participants attain their maximum risk in the third time period (12 years), where almost 4% of them divorce. In addition, a second, and lower, peak in the risk of first divorce is still observed for both groups, but at different later times: at period 9 (36 years) for the degree holders and at period 10 (40 years) for those with no college degree. From the fitted survivor functions, we estimate that 85% of the participants who entered their marriages without degrees have not experienced a first divorce by the end of time period 11 (44 years), compared with 91% of those who entered with degrees. These latter estimates of survival probability are very similar to those provided by the earlier fitted main-effects model. Therefore, the time-varying impact of

DEGREE does not affect the long-term probability of 'surviving' a first divorce, through 44 years of marriage; it just distributes the annual risk differentially, depending on educational attainment at marriage.

In general, with these discrete-time methods, you can continue the addition of further predictors and covariates to test hypotheses about their impact on the risk of event occurrence, in the same way as you would with regular linear- or logistic-regression analysis. You simply include the new variables in the person-period dataset and add them as main effects, or test their interaction with time, as we have done above with predictor *DEGREE*. You can also test for interactions among new substantive predictors themselves, in the usual way, by forming and adding the relevant cross-products. With discrete-time hazard modeling, all of the standard skills that you already possess in the credible modeling of relationships between outcome and predictors carry over into the investigation of risk, making it something that is readily available to scholars throughout the social and behavioral sciences.

Conclusion: Extending Discrete-Time Survival Analysis

We have used our limited space here to introduce the methods of discrete-time survival analysis. However, these methods can be extended easily in important ways, and we invite you to follow up on these extensions by consulting our companion volume (Singer and Willett, 2003) and those of our colleagues (Allison, 2010; Hosmer and Lemeshow, 2002). Below, we touch briefly on the most important extensions.

First, the type of event does not matter, as long as you can define and detect it explicitly. Thus, you can use survival methods to model the risks of marriage and divorce, as easily as milestones in the educational or professional career. Other potential questions could involve the onset of reckless behavior, such as alcohol and drug abuse during adolescence, or relapse to those addictions following treatment. Or, if you can identify explicit stages in cognitive, affective, or moral development with clarity, then their occurrence and timing also offer fertile ground for survival analysis.

Second, discrete-time hazard models can easily incorporate time-varying predictors, whose values differ over time. You have actually seen this implicitly in Model C, because the values of the cross-product of *DEGREE* and time that served to represent our two-way interaction are time varying in value. However, the utility of these methods for modeling the impact of time-varying predictors is broader than this. For instance, had we possessed time-varying information on the educational attainment of each participant, during marriage, rather than only knowing whether they had a college degree at the start of their marriage, we could have treated educational attainment as a time-varying predictor, updating its values in each row of the person-period dataset as the participant acquired more education, and including the now time-varying predictor in another discrete-time hazard model.

Third, as in most statistical modeling, discrete-time hazard models can be extended to include nonlinear effects of predictors, both temporal and substantive. In additional work with our WLS example, not reported here, for instance, we showed that the general specification for time could be replaced parsimoniously by a smooth quartic polynomial specification of the time predictor, without a dramatic reduction in goodness-of-fit. Of course, such nonlinear specifications could also be used with substantive predictors such as AGE at first marriage, if we were to add it to the model as a predictor of divorce. (Incidentally, we do find age at marriage to affect the risk of divorce – those who married younger were at much greater risk of divorce, especially in the early years of their marriage.) Generally, when needed any kind of transformation of the predictors can be incorporated into survival models. By the judicious use of both continuous and dichotomous versions of time, for example, you can specify spline and segmented profiles for the risk of event occurrence. The application is very broad.

Fourth, although we focused here on the risks of the single event of first divorce, you are not limited to investigating the occurrence and timing of events that occur only once over the lifetime. Survival methods extend readily to the modeling of repeated events, as when a first marriage and divorce are followed by a second, a third, and so on. The occurrence and timing of such 'multiple spells' can be modeled simultaneously in a single discrete-time hazard model expanded to incorporate dichotomous predictors to distinguish the spells. We describe this process in a technical paper (Willett and Singer, 1995).

Fifth, you can extend the basic discrete-time hazard modeling strategy to a 'competing-risks' condition, in which individuals can occupy three or more states, all of which compete for attention. Thus, you might examine the termination of marriage while treating the death of the respondent, the death of their spouse, or divorce as three viable events that 'compete' to end marriage. The extension is straightforward. Under a competing-risks assumption, a participant whose 'life' is terminated by one of the several competing events is simply censored on the others. This requires some minor modifications in the person-period dataset, but analyses remain the same.

Finally, the methods of discrete-time survival analysis can be extended to the case of continuous time. We ourselves have found discrete-time methods to be the most useful, because the event-history data that we encounter the most often are collected in discrete time and the principles underpinning the strategy are simple and conceptually appealing. However, a parallel methodological development, referred to as 'Cox-regression analysis,' is available for handling event-histories measured continuously (Cox, 1972). We also describe these latter methods in our companion volume (Singer and Willett, 2003). Reassuringly, as the width of discrete-time periods tends to zero, the findings of discrete- and continuous-time survival analysis converge.

Sustainability: A Dialog of Values

John Blewitt, Aston Business School, Aston University, Birmingham, UK

Published by Elsevier Ltd.

Abstract

Sustainable development and sustainability are related concepts whose origins can be traced to the nineteenth century but have gained increasing prominence from the middle years of the twentieth century. Increasingly, scientists, business leaders, academics, politicians, and other leaders have recognized that the dominant model of industrialization, economic growth, and development was exceeding the natural biological limits of what the planet could practically sustain. This has led to a series of ongoing international conferences attempting to envisage theories, concepts, and practices that could reconcile sustainability with a development "that meets the needs of the present without compromising the ability of future generations to meet their own needs."

Some History

Until the industrialization of Europe in mid-eighteenth century, wood was the primary material used for fuel, construction, smelting, and shipbuilding. World trade and the navies of the great maritime powers relied on a seemingly inexhaustible supply of timber. But these people were wrong. Although timber is a renewable resource European nations were harvesting more trees than were being planted and nurtured to maturity. Governments in Britain, France, and particularly Germany slowly recognized that consuming so much timber was unsustainable. In *Sustainability: A Cultural History*, Ulrich Grober (2012: 88) discusses how many foresters and enlightened government ministers, including Johan Wolfgang von Goethe of Weimar, believed that 'the true capacities of the forests' should become the basis for their use and exploitation. The modern science of ecology, the concept of sustainability, and the practice of sustainable development were born. Many years later in the mid-twentieth century, Rachel Carson's (Carson, 1962) *Silent Spring*, first published in 1962, analyzed the devastating ecological impact chemical pesticides and huge agricultural businesses were having on the American countryside. This seminal book probably has come symbolizing the beginning of what became known as Earth Politics and inspired for establishment of the modern environmental movement.

In Europe and America the 1960s' and 1970s' economic growth and rampant consumerism led to a growing recognition that Western lifestyles and the ideology of development were compromising the ecological balance, stability, and security of the planet. This concern was amplified when a single image of our lonely and luminous planet Earth, taken from the Apollo Eight spacecraft in 1968, was published and disseminated across the world. The photograph, titled Earthrise, was interpreted by many people as revealing the fragile beauty of our blue planet. It had a truly powerful emotional impact. In 1972, a further photograph from the Apollo Project, Blue Marble, soon became the most published image in history thereby gaining an iconic status among many new sustainability advocates and the wider environmental movement. World famous pressure groups were formed, like Friends of the Earth and Greenpeace, and soon hit the headlines. Ecologically minded writers, artists, poets, and scientists, following in Rachel Carson's footsteps, came to prominence. Theodore Roszak's *Where the Wasteland Ends* (1972), and E.F. Schumacher's game changing *Small is Beautiful* (1973) were international best sellers and from the dismal science of economics Kenneth E. Boulding's *The Economics of the Coming Spaceship Earth*, created a metaphor which captured the public imagination. In this work, he clearly stated there were no unlimited reservoirs of anything and that humanity needed to find its place in the planet's cyclical ecological system which, although capable of continuous reproduction, continually needed inputs of energy to maintain itself. Thus, in 1970, Earth Day was the first major environmental event to have any real social, public, and cultural impact was held in the US. Two years later, in 1972, a global think tank known as The Club of Rome published what would soon become its landmark study, *Limits to Growth*, and the first serious international conference on global environmental issues occurred at the United Nations Conference on the Human Environment in Stockholm, Sweden.

Limits to Growth

The Club of Rome's report (Meadows et al., 1972) combined an optimism regarding the human potential to innovate and capacity to transcend environmental and demographic limitations with a series of detailed models and scenarios warning that if existing trends continued, negative economic and ecological consequences would undoubtedly follow. The Club of Rome's model for global development was constructed to investigate five major trends – accelerating industrialization, rapid population growth, widespread malnutrition, depletion of nonrenewable resources, and a deteriorating environment (*see also* Environment and Development; Limits to Growth). The authors looked to the future and posed some difficult questions: What do we want our world to be like? Can we continually keep expanding production and consumption? The answer was a clear: No. But achieving a self-imposed limitation to economic growth would require considerable effort, a massive change of mindset, and political practice. It would necessarily involve learning to do many things in new ways and even to stop doing others. It would tax the ingenuity, the

flexibility, will power, moral sense, and self-discipline of the human race. It would create disagreement and conflict and challenge many vested economic and financial interests. Bringing a deliberate, controlled end to growth would clearly be a tremendous challenge, not easily met and extremely difficult to countenance by governments, businesses, and ordinary citizens from across the world. There were many doubts, arguments, and questions too. Would the final result be worth it? What would humanity gain by such a transition and what would it lose? In the 30 years preceding the report publication, global economic growth continued and the world's unsustainable practices became increasingly obvious. Thirty years later, three of the original authors produced an update (Meadows et al., 2005). They reviewed many of the debates and criticisms their earlier work had generated, analyzed new evidence, rectified the flaws in, and sharpened their models and as a consequence amended their position somewhat. Nonetheless, they firmly reaffirmed and demonstrated that the theory of necessary limits to growth remained valid, vital, and significant. Indeed, more so in the twenty-first century than ever before.

Toward Sustainable Development

At the same time as the Club of Rome was doing its work, the General Assembly of the IUCN (World Conservation Union), a body established a little after World War II, met in New Delhi. Together with the newly formed World Wildlife Fund (later remained Worldwide Fund for Nature), the IUCN focused on developing new strategic thinking for animal and habitat conservation, ecological restoration, and human well-being. The relatively unfamiliar and under utilized concept 'quality of life,' as oppose to the more material and comprehensible concept 'standard of living,' became the centerpiece of IUCN thinking and policy development. The IUCN's aim was to intelligently link cultural diversity with ecological or what has become known today as biodiversity. In 1980, the IUCN published its World Conservation Strategy and so launched into the global public sphere the rather hopeful concept of sustainable development. For the IUCN, humanity's relationship with the biosphere would continue to deteriorate until a new ecologically sensitive international economic order and a new environmental ethic was developed. Indeed, economic development would continue but it needs to be socially equitable and environmentally sustainable. In the same year, the Brandt Commission published its *North-South: A Programme for Survival* which planted the responsibility for human survival firmly in the political arena at a time when leaders still seemed more concerned with the vagaries, conflicts, and posturing of the Cold War than addressing the equally, and perhaps even more, pressing issues of global poverty, disease, social inequality, injustice, self-determination, human rights, and the constant depletion of the world's natural resources. The Commission did not wish to redefine development, but duly noted:

> One must avoid the persistent confusion of growth with development, and we strongly emphasize that the prime objective of development is to lead to self fulfillment and creative partnership in the use of a nation's productive forces and its full human potential.
> Brandt, 1980: 23

In other words, the Brandt report suggested that development strategy should not be based upon unlimited and infinite economic growth or GDP as the sole measure of progress (*see* Economic Growth). The world as a whole should not use as a model for future generations the ecologically destructive industrial development paths pursued that had created and defined the West. The standard of life is not the same as the quality of life. More stuff does not necessarily mean a better happier life although a certain degree of material wealth and comfort is essential for human and social well-being. Development should focus on nurturing human well-being and ecological sensitivity rather than the relentless accumulation of material products. Every region of the world has its own ecological and cultural heritage and should as a result be enabled to chart its own distinct and distinctive path toward sustainability. Thus, wealth and development took on a qualitative as well as a quantitative aspect. Material and spiritual poverty both need addressing in policy and practice at local and global levels.

In 1983, work started on a major study by the World Commission on Environment and Development that would firmly establish sustainable development as the most significant concept and practice of our time. In 1987, the results were published as *Our Common Future* (the Brundtland Report). More than half of the Commission were representatives from developing countries, ensuring that the global environmental concerns of the developed Western nations would not overwhelm the desire to eradicate problems of human need and poverty. Unlike Brandt, Brundtland did offer the now globally famous definition of sustainable development (WCED, 1987: 43):

> Development that meets the needs of the present without compromising the ability of future generations to meet their own needs.

This definition is still commonly used despite it attracting serious criticisms for perhaps, a term which some came to replace the Cold War notion of the West, inferring that economic growth, industrial modernization, and market imperatives should be key drivers and goals for all nations. Whereas the industrialized North seemed to be, and in many ways still is, concerned with environmental impacts the issues confronting the majority of the South included poverty, health, income, agricultural sustainability, food security, educational opportunity and achievement, shelter, sanitation, desertification, and armed conflict. For the South, economic development including growth was seen as essential and the more ecological concerns of the North were often perceived as being luxuries only the affluent nations could afford and countenance. For others, particularly within the academic world, sustainable development seemed to be either hopelessly vague or a basic contradiction in terms. Whatever the case, sustainable development entered the global policy lexicon and has remained there ever since.

The 1992 Rio Earth Summit

Five years later, in 1992, the UN Conference on Environment and Development, the follow-up to Stockholm, was held in Rio de Janeiro. This meeting, known as the Earth Summit, produced a number of very important agreements, including the Rio Declaration on Environment and Development, the Framework Convention on Climate Change, the Convention on Biological Diversity (CBD), a nonbinding Statement on Forest Principles, and the hugely cumbersome but nonetheless foundational agreement known as Agenda 21. The CBD and the negotiations before and after the 1997 Kyoto Protocol on climate mitigation are two very important examples of multilateral environmental agreements. Maintaining biological diversity is key to maintaining the planet's overall health and those ecosystem services that replenish natural resources and offering all creatures the dynamic equilibrium upon which life depends. Thus, if plant and animal species disappear, as they are doing at an unprecedented rate, then monocultures will emerge which are highly susceptible to disease, the effects of climate change, and other damaging ecological transformations. Industrialized systems of agricultural production have forced governments and the large corporations to recognize that these impacts must be mitigated and managed – biological diversity must be conserved, resources must be used more sustainably, and the material and cultural benefits derived from the planet's genetic resources shared more equitably. Business as usual is no longer an option. Following Rio, many national strategies have been based on these broad international agreements and statements of principle and intent. However, indigenous peoples and local communities have not always found their ideas, values, and needs accepted when the actual implementation processes are enacted but there has more recently been an acceptance that the developed world has a great deal to learn from the traditional ecological knowledge of peoples who retain a close affinity to the natural environment. However, global trade and commercial imperatives have led to rather weak attachments to sustainable development. Probably most depressing have been the limited, tortuous, and hesitant agreements and accommodations around the 1997 Kyoto Protocol – so far the only international, legally binding agreement on climate change.

The realities of climate change, global poverty, economic inequality, and water shortage also highlight the significance of gender in sustainable development. Although much NGO attention has focused inevitably on the appalling hardships many women experience, gender issues cannot be separated from wider social, cultural, or environmental concerns which has sometimes been the case. The Women's Environment and Development Organization (WEDO) has campaigned vigorously to combat the intergovernmental blindness to the gender implications of environmental policy and actions. Global climate change negotiations, including the Kyoto Protocol and the reports of the United Nations' Intergovernmental Panel on Climate Change, concentrate almost exclusively on reducing greenhouse gas emissions, largely ignoring the wider social and gender impacts. A United Nations Environment Programme (UNEP) (UNEP, 2006) survey, "Gender mainstreaming among environment ministries," discovered that just two countries involved in climate change activities had incorporated a gender perspective. However, as well as arguing that women often suffer disproportionately from unsustainable development, UNEP frequently promotes women as important agents for community empowerment, social leadership, and positive change. As the World Conservation Union has shown (IUCN, 2007), communities often cope more effectively during natural disasters when women play a leadership role in early warning systems and post-disaster reconstruction than when they do not. The IUCN also notes that women's local knowledge and skills offer tangible benefits such as Inuit, the women of Northern Canada, having a deep understanding of weather conditions because of their traditional responsibility for evaluating hunting conditions. When a drought occurs in the small islands of Micronesia, local women who have a sound knowledge of island hydrology find potable water by digging new wells. WEDO (2007: 3) adds that women tend to share information related to community well-being, choose less polluting energy sources, and adapt more easily to environmental changes when their families 'survival is at stake'.

The 40 chapters of Agenda 21 offered an action plan for sustainable development, integrating environmental with social and economic concerns, and articulating a participatory, community-based approach to a variety of issues, including population control, transparency, partnership working, equity and justice, and placing market principles within a regulatory framework. Local Agenda 21 (LA21), its local realization, was not legally binding, although by the end of 2000, many countries including the UK, had detailed policies and elaborate frameworks for sustainable development at local and regional levels. Municipal governments in many countries have taken a strong lead in global sustainability and today many of the world's 'global cities' have made considerable progress toward realizing sustainability goals. With an increasingly urban global population the sustainability of towns and cities can only increase in importance (*see* Urbanization; Development and Urbanization). In those, particularly Scandinavian countries where local government has a considerable degree of autonomy to raise income locally and regulate environmental matters, LA21 has been highly successful inspiring many communities to take action. However, throughout the world, even though local government priorities and powers may differ, global structures of economic, financial, and political power which include support for the neoliberal free trade system have compromised some attempts to fashion sustainable development from the bottom up. The local cannot be disassociated or disconnected from the global, conceptually or practically. Nonetheless, the LA21 process continued with, from 2002, Local Agenda 21 turning into Local Action 21. In 2004, the Aalborg Commitments was published, showing many local authorities within the European Union to be firmly embracing the need for urban sustainability and good governance. In addition, many grassroots movements such as those associated with Transition Towns have more recently made considerable progress with local municipalities becoming partners in rather than leaders of local actions such as local food growing, community enterprise and the creation of energy or carbon descent plans in our era of Peak Oil (*see* Mineral Resources, Limits to: The Case of Peak Oil).

Rio + 10, and + 20

Rio was, despite all the compromises and shortfalls, a significant achievement which over the years has gained in stature and authority. Paradoxically this enhanced status has grown because of the reluctance of the US to accept sustainable development policies, its frequent refusal to recognize the importance of the precautionary principle as a guide to environmental law, and the failure to be a party to global agreements on cutting greenhouse gas emissions. America's continuing support for neoliberal economic globalization has also had damaging consequences not least to the global economy following the financial crash of 2007–08 but also to the global environment more generally. However, the early years of President Obama's second administration has seen a shift in tone, policy, and action regarding the environment including particularly the increasingly evident impacts of climate change. Also, and again somewhat paradoxically, the fact that the Rio Declaration was seriously criticized by many radical green groups made its achievements all the more valuable and politically symbolic.

In 2002, the Johannesburg (Earth) Summit reviewed a decade of progress. The tensions apparent in 1992 remained obvious to all although the final declaration noted that global disparities in wealth and environmental degradation now risked becoming entrenched. Unless the world decides to act in a manner that fundamentally changes the lives of the poor, many citizens could lose confidence in democratic systems of government perceiving their representatives as little more than 'sounding brass or tinkling cymbals.' Indeed, general public disillusion and disaffection with established political institutions, ostensibly democratic procedures and processes, have characterized a great deal of the politics and protest occurring in the first decade or so of the twenty-first century at every spatial scale – the global, national, and local. At Johannesburg, little was said about financing international development, though in the same year, at an International Conference on Finance for Development in Monterrey, northeast Mexico, a consensus was reached on financing sustainable development, fostering health and education, providing shelter, eradicating poverty, and sustaining economic growth. The role of trade and overseas development aid, the importance of debt reduction and good governance in the developing world, and the mobilization of national economic resources and external investment were directly addressed although the perennial problems remained unresolved. Economic crises, the conference report stated, underscored the importance of the need for effective social safety nets.

The twenty-first century has witnessed progress, with regard to sustainable development, stall. In December 2009, a major climate conference was convened in Copenhagen to decide the successor to Kyoto but no legally binding treaty emerged from the tortuous negotiations that were frequently deadlocked (*see* Climate Change). China, India, and the US were each in turn blamed for the conference failure by politicians from other nations, international NGOs, and media commentators. However, delegates did agree that global warming should not exceed 2 °C but set no actual targets for cutting emissions. For some critics the real culprits were not the negotiators at Copenhagen but a general lack of political will and leadership in most countries. However, over the next few years talks continued at Cancun, Durban, Bangkok, Bonn, and in November–December 2012 in Doha, Qatar. A number of documents were produced at Doha, collectively known as The Doha Climate Gateway, which extended the Kyoto protocol to 2020 but limited the scope of global carbon emissions to 15% because Japan, Russia, Canada, and the US did not participate. Additionally, because China, India, and Brazil were still classified as developing nations at Kyoto, they have not been subject to agreed emission reduction targets. Climate campaigners and others reviewing these negotiations have not surprisingly expressed their exasperation and frustration. In 2011, Kevin Anderson and Alice Bows published a paper for the Royal Society in the UK warning that there was 'no chance' of keeping global warming below 2 °C and in any case recent studies relating to the impacts associated with such a rise have been revised upwards from 'dangerous' to 'extremely dangerous.' Consequently, they write (Anderson and Bows, 2011: 41), "with tentative signs of global emissions returning to their earlier levels of growth, [the year] 2010 represents a political tipping point." Energy expert Dieter Helm (2013) argues that massive investment needs and rigorous economic instruments are needed to combat climate change and businesses, governments, and citizens need to change their behavior radically. We are in a hole, he writes, but we can stop digging.

Although progress since the first Earth Summit in 1992 was carefully evaluated, commemorated, and celebrated at the Rio+20 Summit no new agreements or targets were issued in 2012 but there were plenty of 'reaffirmations' and 'recognitions' in the conference's final statement, The Future We Want (United Nations: 2012: para19; p.4). Indeed, the clear admission expressed in the clause, "we emphasize the need to make progress in implementing previous commitments," indicates both why and how so many delegates felt so deflated with the conference outcomes. Much of the debate was polarized around the meaning of the 'green economy' which for many seemed to coalesce around the desire for green energy technologies rather than defining the need for a new economic paradigm that favored social equity and quality of life above economic growth. UNEP, for example, clearly advocated and advocates a series of policy prescriptions characterized by the key principles of ecological modernization, the low carbon economy, and eco-efficiency. At a moment when the global economy was experiencing considerable stress as a result of the serial failures of finance capitalism, the Rio+20 vision for the future was hesitant, modest, and accommodative. Having said this, if progress was made at Rio in 2012 it was in realizing that no single assessment matrix for sustainable development had been previously devised and accepted. Consequently, an immediate task for the future became the fashioning of a set of sustainable development goals (SDGs) which in effect would supersede the Millennium Development Goals formulated at the turn of the century which largely focused on human health, poverty eradication, and general well-being. These new SDGs would be action orientated, concise, easy to communicate, limited in number, aspirational.

Sustainability as a 'Dialogue of Values'

There have been many academic critiques of the various discourses on sustainable development (Blewitt, 2014). For many observers the sustainable development has an equivocal relationship to the dominant economic growth paradigm and has also been informed by the residue of colonial thought processes which have disempowered many rural populations and the urban poor in the developing world. Although some critics acknowledge that the idea of sustainable development includes notions of plurality and dialogue, the commitment to and attraction of biotechnology, Western science, the commoditization of biodiversity via corporate patenting and intellectual property rights, has marginalized the many who still depend on their land for their livelihood. Indeed, a great deal of the discussion around green business still focuses on technological solutions and eco-efficiency – doing more with less – although there are signs that some very large business corporations are taking sustainability and social responsibility extremely seriously. Unilever is often cited as an example of a company in the process of changing its business model in a major way.

However, for conservation and sustainability academic Bill Adams (2001: 381) the fact remains that in the developing world, the global South, there is "no magic formula for sustainable development," no easy reformist solution to poverty and that, contrary to dominant practice, development "ought to be what human communities do to themselves" rather than what is done to them by states, bankers, experts, agencies, centralizing planners, and others. Instead, a 'green development' is required for which there can be no hard and fast blueprints because there is an overwhelming need to be open-ended, open minded, participatory, and overtly democratic. Green development is about who has the power and how it is managed. It is about empowerment and self-determination. For the eco-economist Ignacy Sachs (1999), there is a real need to emphasize the importance of social sustainability as a counterweight to the ideological and political dominance of the economic discourse on growth. Social sustainability introduces the need to address the recurring incidents of war and serious violence, state oppression of citizens, and a growing sense that there is a lack of meaning in today's world. Thus, Ignacy Sachs argues that development is akin to liberation and transformation if understood as a self-organizing and intentional process which actually frees people from poverty and exploitation. However Sachs, like the World Bank, recognizes that trade-offs will occur but some are totally, ethically, unacceptable. He writes (1999: 33),

> Concern for the environment should not become a diversion from the paramount imperatives of social justice and full democracy, the two basic values of whole development.

The Indian development economist and philosopher Amartya Sen (1999) has argued that realizing human capabilities in a sustainable society means equity, democracy, human and civil rights, and a continuing enhancement of people's ability to do what they have good reason to value. It also entails envisioning alternatives, acting and thinking differently, and most importantly having the capacity, freedom, and opportunity to do so. It will involve protecting biodiversity because human social and economic relationships are closely interwoven in a coevolutionary relationship with the biosphere. It means conceiving and practicing development holistically and systemically, not simply economically or socially, politically or anthropocentrically. What renders sustainability and sustainable development especially valuable is their resilient compatibility which affirm the ideas of freedom, of fulfillment, of being and securing what is truly valuable – the freedom to achieve, to effect solidarity with others, to develop capabilities and alternatives, and to live justly and meaningfully (Sen, 1999). Thus, social and environmental justice is essential to the satisfaction of human needs, of securing inter- and intra-generational equal opportunity, partnership, and cooperation. For Sen, this is the meaning of development within sustainable development.

For environmental scientist Richard B. Norgaard (1994), Western science, the environment, and material resources are connected within mutually interactive coevolving systems where one does not control any of the others. In nineteenth-century Europe, the application of scientific knowledge facilitated the use of coal and hydrocarbons which in turn directed and intensified scientific activity, agricultural, technological, and industrial development and the emergence of a new social, moral, and political order. Urbanization, class division, multinational business, global trade, and bureaucratic management systems helped concentrate economic and political power and the strategy of imposing this Western practice and ideology of development on non-Western others. Consequently, "correcting the unsustainability of development is not simply a matter of choosing different technologies for intervening in the environment. The mechanisms of perceiving, choosing, and using technologies are embedded in social structures which are themselves products of modern technologies" (Norgaard, 1994: 29). This coevolutionary approach to historical explanation offers tremendous insights but does not help us predict the future, for in this theory there can be no simple causal relationships. Prediction can therefore becomes either dangerous or ridiculous or both.

Given this, the concepts of and practices associated with sustainable development and sustainability therefore encompass multidimensional social, ecological, and economic goals and perspectives whose breadth and unscientific nature has led to many attempts over the decades to formulate precise sustainability measures, tools, indicators, and frameworks as well as the vaguer aspirational goals and intended inspirational aims articulated in various declarations, treaties, and political speeches. However, as sustainable development does not endorse 'calculative thinking' as a sole or perhaps even the most way of understanding what is the future we actually want and can achieve. Perhaps then, it is the sociologist Blake Ratner's notion of sustainability as a 'dialogue of values' which points to a way of effectively salvaging, understanding, and engaging with the various theories, values, perspectives, and assumed and actual contradictions of sustainable development. He identifies three basic tendencies in sustainable development practice, namely the technical, ethical, and dialogic. He writes (2004: 62),

> The sustainability concept is meaningful, therefore, not because it provides an encompassing solution to different notions of what is good, but for the way it brings such differences into a common field of dispute, dialogue, and potential agreement as the basis of collective action.

One of the main obstacles to developing a common conceptual framework or dialogue of values incorporating social, economic, and ecological concerns is the lack of genuine consensus among experts in each discipline concerning how ecological, economic, and social systems relate to one another. The resulting 'trifocal' vision makes understanding the world, international and national policy development, and effective action a major challenge. This is sometimes exacerbated by occasional tendencies for one group of experts to see their approach as being more fundamental than any other. When this happens, dialogue can become extremely difficult. Interdisciplinary and transdisciplinary approaches need to be discussed and enacted within and outside the academy. Political and practical strategies, policies and actions facilitating the emergence of conditions allowing for possible reconciliation between perspectives are essential. A recognition that systems thinking and concepts drawn from the study of nature and ecology can be applied, adapted, and developed in new contexts, such as education, economics, and politics, is an important way forward (*see also* Human Ecology; Social Ecology). Only if this is possible, can there be an effective understanding of, and engagement with, the overlapping and interconnected systems making up the biosphere, the economy, and human society. The intellectual basis for this engagement lies in the processes of dematerialization and resocialization of economic activity and by placing greater significance to well-being rather than materialistic criteria for assessing progress and development. To effect this democratically, there needs to be an authentic social dialogue on sustainability values and sustainable development policies. Without such dialogue political decision-making is likely to be blinkered, misinformed, or uninformed.

Ultimately, as Canadian academic John Robinson (2004) argues, sustainability is a political act, and what must inform this act is learning, understanding, and agreement. Meanings and practices will change as the world changes, as our skills, knowledge, and capabilities develop, and as communication and dialogue continues over time. From the neighborhood to global levels, different interests come together and sometimes collide but it is only through discussion, critical reflection, and dialogue that agreement and action on sustainability can come about. A step toward this is the remarkable document known as The Earth Charter which could only have been reached by people listening, talking, and learning from one another … and being willing to do so. Talk can become or lead to action for different countries have different levels of development, different values, cultures, and traditions. They are endowed with differing amounts of natural resources and so have, certainly according to Brundtland, differentiating responsibilities in promoting and realizing SDGs. This very heterogeneity has and can continue to allow a coming together, and an identification of common ground on which to build further action toward sustainability.

Conclusion

One of the main reasons why 'sustainable development' – the process – and 'sustainability' – the end in view or goal – have generated so much discussion is because they tend to reflect the political and philosophical value base of those involved in the conversation. John Robinson (2004: 370) prefers the term sustainability to sustainable development because, as he writes, it "focuses attention where it should be placed, on the ability of humans to continue to live within environmental constraints." For those who want an unambiguous scientific, technical, discipline-specific, and/or operationable definition, this causes problems unless a great deal is ignored or discounted. What is needed, then, and what the creative ambiguity surrounding 'sustainability' can offer, is the possibility of integration, synthesis, and synergy – of a social learning process that bridges the divisions between the social and ecological, the scientific and spiritual, the economic and the political. Thus, in practice, technical fixes are necessary but not sufficient if ecological, economic, and social imperatives are to be reconciled. For John Robinson, this cannot be done scientifically, only politically – in dialogue and in partnership, making sustainability "the emergent property of a conversation about what kind of world we collectively want to live in now and in the future." Finally, it is probably pragmatic, at the very least, to acknowledge Robinson's important insight (2004: 382) that within the field of sustainability multiple conflicting views do clearly exist and it may not always be possible to find ways of reconciling them.

> In other words, no single approach will, or indeed should be, seen as the correct one. (...). [W]e are inescapably involved in a world in which there exist multiple conflicting values, moral positions and belief systems that speak to the issue of sustainability. While it is crucial to identify points of empirical disagreement and to resolve those with better research and analysis, the ultimate questions are not susceptible to empirical confirmation or disconfirmation. What is needed, therefore, is a process by which these views can be expressed and evaluated, ultimately as a political act for any given community or jurisdiction.

In this way, 'sustainable development' and 'sustainability' may productively function as a heuristic, in other words a learning process by which people are enabled to find things out for themselves and to fully appreciate the contested nature of knowledge, the environment and sustainability, and the impact human actions have upon the Earth. Human life and the environment are not two separate entities: we are on and of the world. We must think and act wisely. We share the planet with other creatures and act accordingly in a just and equitable manner.

Sustainability and Sustainability Science

Robert W Kates, Trenton, ME, USA

Abstract

Sustainability, beyond its dictionary meaning, combines economic and human development with environmental maintenance, preservation, or improvement as sustainable development. It is characterized by various indicators, scenarios, goals, and targets. As a new subfield of science, it has an active solution-oriented research agenda, a theoretical perspective in coupled socio-environment systems, a decade of major publication, dedicated centers and institutes in many parts of the world, and a growing number of degree programs at every level.

Sustainability is everywhere, as in its dictionary use as the ability to be maintained at a certain rate or level, but also linked to economic and human development, applied to environmental maintenance, preservation, or improvement, or increasingly as a new subfield of science. How widespread its use has become is illustrated by Bettencourt's and Kaur's (2011) extended analysis. They assembled a database of scientific publications in English written between 1974 and 2010 that contained in their title, abstract, or key words 'sustainability' and/or 'sustainable development,' but eliminated items that simply used sustainable as in general usage. The data set contained about 20 000 papers, authored by about 37 000 authors found in 174 countries and in 2200 cities. The range of publications is quite varied as illustrated in the word cloud (Figure 1). Sustainable development, environmental sustainability, and sustainability science constitute the substance of this article.

Sustainable Development

The reconciliation of society's human developmental goals with the planet's environmental limits over the long term is the foundation of the concept known as sustainable development. The origins of sustainable development can be traced back through the 1980 World Conservation Strategy and the 1972 Stockholm Conference on the Human Environment to the early days of the international conservation movement (O'Riordan, 1988; Adams, 1990). But the contemporary linking of environment and development is now a quarter of a century old, stemming from *Our Common Future*, the 1987 report of the World Commission on Environment and Development (also known as the Brundtland Commission). The Commission defined sustainable development as the ability of humanity "to ensure that it meets the needs of the present without compromising the ability of future generations to meet their own needs" (WCED, 1987).

An extraordinarily diverse set of groups and institutions have taken this widely accepted statement of sustainable development and projected upon it their own hopes and aspirations. While sharing a common concern for the fate of the earth, proponents of sustainable development differ in what they think is to be developed, what is to be sustained, how each is related to the other, and for how long a time.

The most common view of what is to be developed is the economy that provides employment, needed income, desired consumption, and the means for investment in physical and human capital as well as environmental maintenance and restoration. An alternative emphasis is on people-centered human development which focuses on the quantity of life as seen in the survival of children and their increased life expectancy and the quality of life through

Figure 1 Word cloud for bigrams titles of sustainability papers. Bigrams (consecutive two-word combinations, obtained after frequent stop words are removed) often give a better sense of subjects addressed than single words. The frequency of *sustainable development* has been reduced by 35%, so that other terms would be more visible. Taken from Figure S3 in Bettencourt, L.M.A., Kaur, J., 2011. The evolution and structure of sustainability science. Proceedings of the National Academy of Sciences 108, 19540–19545 with permission of PNAS.

education and equal opportunity. Finally, some discussions of what is to be developed emphasize society itself, addressing the well-being and security of national states, regions, and institutions.

Environmental Sustainability

The most common view as to what is to be sustained are planetary life support systems, particularly those supporting human life. These systems include natural resources as well as environments that provide food, fiber, water, regulate atmosphere, climate, disease, pests, water, and culture as aesthetics, spirit, and recreation (Daily, 1997). The Millennium Ecosystem Assessment (MEA, 2005) found that these ecosystems have been changed more in the past 50 years than in any comparable period of human history, primarily to provide increased amounts of fiber, food, fuel, timber, and water. These changes have led to substantial net gains in economic development and human well-being, but not for all people and locations. The environmental systems that provide these services have been degraded or used unsustainably in many places and with possibilities of even more abrupt, rapid, or irreversible change that may well diminish the benefits to future generations (Turner et al., 1990).

Contrasting this anthropocentric view of nature as human life support is one of sustaining nature itself in all its biodiversity and assemblages of life forms. These ought to be sustained, not only for their utilitarian service to humans, but because of the moral obligations of humanity arising either as 'stewardship' – still acknowledging the primacy of humans – or as a form of 'natural rights' in which earth and its other living things have equal claims for existence and sustenance. Also for some, cultural diversity is seen as a counterpoint to biological diversity, with various communities that include distinctive cultures, particular groups of people, and specific places that need to be sustained.

Linkages between Development and Environmental Sustainability

The relationship between what is to be developed and what is to be sustained also differ. Some conceptual statements provide equal emphasis to both; others while paying homage to sustainable development, seem to be saying 'sustain only' or 'develop mostly' or 'sustain or develop subject to some minimal constraint on the other.' Similarly the implied time horizons for sustainable development differ. There is universal acceptance that such time horizons are intergenerational, but these then range between a single generation of 25 years, several generations, or as an unstated, but implicit, forever. Each of these time periods present very different prospects and challenges for sustainable development. Over the space of a single generation, almost any development appears sustainable, over an infinite forever none do.

In 2002, these relationships were expanded when the World Summit in Sustainable Development addressed growing concerns over the defining of development as economic development, while ignoring human development, and issues of equity and social justice. In its Johannesburg Declaration (2002) it asserted "a collective responsibility to advance and strengthen the interdependent and mutually reinforcing pillars of sustainable development – economic development, social development and environmental protection – at local, national, regional and global levels." These three pillars of sustainable development, i.e., economic, social, and environmental, are widely used, but there has been no agreement on the specific content of the three pillars, especially the social pillar.

Web searches can find three major variants of social development. There is a generic non-economic social designation described as 'social,' 'social development,' and 'social progress.' An alternative uses terms such as 'human development,' 'human well-being,' or just 'people' to address human development as opposed to economic development, while such terms as 'social justice,' 'equity,' and 'poverty alleviation' characterize concerns over justice and equity. Still the commitment to the three pillars persists and in the most recent of the world summits, Rio +20, while generally found disappointing (Halle, 2012), restated in its very first paragraph its declaration that we, "renew our commitment to sustainable development, and to ensure the promotion of economically, socially and environmentally sustainable future for our planet and for present and future generations."

Indicators and Scenarios

To add detail to sustainability, major efforts were made early to choose indicators of sustainable development in order to indicate directions of action or to measure progress of a sustainability transition (UN-CSD, 1996; Moldan et al., 1997; Meadows, 1998). These continue and if global, national, and local efforts are included, there are hundreds of efforts to identify appropriate indicators and to measure them. Typical of these efforts is the set of 40 economic, environmental, and social indicators for the US drawn from existing data sets by an intergovernmental committee for each of the three pillars of sustainable development (**Table 1**).

A review of global, regional, country, or local indicator efforts (Parris and Kates, 2003a) found that large numbers of indicators were considered and selected, with 40 or more indicators as in **Table 1** were quite common. But despite the intergenerational perspective of the standard definition of sustainability, the emphasis of most indicator studies is on the present or very short term. The large number of indicators seems to emerge from a participatory process where the ostensible need for indicators actually enables a broad discussion by very diverse sets of stakeholders as to what sustainable development should be and a negotiation over their differing views and aspirations. Thus to overcome the essential ambiguity of 'sustainable development' and to be inclusive of stakeholder views, the number of indicators becomes very large.

In contrast to indicators such as these that can inform society to what extent progress is being made in a transition toward sustainability, alternative pathways for a transition were explored through long-range development scenarios that reflect the uncertainty about how the global system might unfold. While most are rigorous, using the insights of science and modeling, these scenarios are told in the language of words as well as

Table 1 Sustainable development in the USA: an experimental set of indicators

Economic	*Environmental*	*Social*
Capital assets	Surface-water quality	Population of USA
Labor productivity	Ratio of renewable water supply to withdrawals	Life expectancy at birth
Domestic product	Fisheries utilization	Births to single mothers
Income distribution	Acres of major terrestrial ecosystems	Children living in families with only one parent present
Consumption expenditures per capita	Invasive alien species	Educational achievement rates
Unemployment	Conversion of cropland to other uses	Educational attainment by level
Inflation	Soil-erosion rates	Teacher training level and application of qualifications
Investment in R&D as a percentage of GDP	Timber growth to removals balance	People in census tracts with 40% or greater poverty
Federal debt to GDP ratio	Outdoor recreational activities	Crime rate
Energy consumption per capita and per $ of GDP	Contaminants in biota	Participation in the arts and recreation
Materials consumption per capita and per $ of GDP	Quantity of spent nuclear fuel	Contributing time and money to charities
Homeownership rates	Identification and management of superfund sites	
Percentage of households in problem housing	Metropolitan air quality nonattainment	
	Status of stratospheric ozone	
	Greenhouse gas emissions	
	Greenhouse climate response index	

numbers because assumptions about culture, values, lifestyles, and social institutions require qualitative description. Sets of scenarios were created that reflect current trends and reform proposals, various forms of social and environmental breakdown, and more fundamental transitions or transformations (Hammond, 1998; Raskin, 2002; Carpenter et al., 2006).

Goals and Targets

A transition to sustainability is also marked by specific and concrete goals that become targets for action that both define sustainable development and illustrates what it seeks to achieve (Parris and Kates, 2003b). For example, consider three sets of goals that use different time horizons. They are: (1) the short-term (2015) goals of the Millennial Declaration of the United Nations; (2) the two-generation goals (2050) of the Sustainability Transition of the NAS-BSD; and (3) the three generation (beyond 2075) goals of the Great Transition of the Global Scenario Group.

Millennial Declaration of the United Nations

In September 2000, the General Assembly of the United Nations adopted some 60 millennium goals that addressed peace, development, environment, human rights, the vulnerable, hungry, and poor, Africa, and the United Nations. Many of these contained specific targets to be reached by 2015 and for eight of the major goals (with 21 targets) progress is monitored by international agencies (United Nations, 2013) Three major goals address hunger and poverty, education, and gender equality. Three goals address health related to children, mothers, and specific diseases. Another is concerned with environmental sustainability, but only as drinking water and sanitation availability, and one on slum improvement. The last goal is to attain a global partnership for development including aid, debt, trade, and technology, with special attention to the least-developed, landlocked, and small island states.

As of 2012, 3 years before the 2015 achievement date, a number of the targets have been or will soon be achieved (United Nations, 2013). The first goal, the target of reducing extreme poverty by half has been reached 5 years ahead of the 2015 deadline, although the target of halving hunger will not be reached. Universal primary education will not be reached but major progress has been made especially in sub-Saharan Africa. For the third goal of gender equality, primary school enrollment of girls has already equaled that of boys. Among the health goals, there has been accelerated progress in reducing child but not maternal mortality, tuberculosis will be halved by 2015, and progress will be made on malaria and HIV-AIDS. For environmental sustainability, the target of halving the proportion of people who lack dependable access to improved sources of drinking water was met by 2010 and conditions for more than 200 million people living in slums have been ameliorated – double the 2020 target. Plans are underway for a new set of goals and targets beyond 2015.

Sustainability Transition of the NAS-BSD

From 1995 to 1999, the National Academy of Sciences-National Research Council's Board on Sustainable Development (1999) focused on a two-generation time horizon to address the minimal needs of a global population of 9 billion in which the world provides the energy, materials, and information to feed, nurture, house, educate, and employ the many more people of 2050, and reducing their hunger and poverty – while preserving the basic life support systems of the planet. They called this a sustainability transition.

Specific targets for these goals for human well-being and environmental preservation had been defined over the previous decades through extensive processes of international political debate and intergovernmental action. In the area of

human needs, internationally agreed-on targets existed for providing food and nutrition, nurturing children, finding shelter, and providing an education, although not for finding employment. Thus, there was an implicit hierarchy of needs that favored children and people in disasters, and favored feeding and nurturing first, followed by education, housing, and employment.

Compared with targets for meeting human needs, quantitative targets for preserving life-support systems were fewer, more modest, and more contested. Global targets existed for ozone-depleting substances and greenhouse gases, and regional targets existed for some air pollutants. Absolute prohibitions (zero targets) existed for ocean dumping of radioactive wastes and some toxics, for the taking and/or sale of a few large mammals (whales, elephants, and seals), migratory birds when breeding or endangered, and certain regional fishing stocks. Water, land resources, and ecosystems such as arid lands and forests had, at best, qualitative targets to achieve sustainable management or restoration. International standards existed for many toxic materials, organic pollutants, and heavy metals that threatened human health, but not for ecosystem health.

In choosing such targets, the Board anticipated the Millennium Declaration goals, with its own analysis of goals and targets. Less sanguine than the UN, the Board determined it would take a generation (25 years) to reach the 2015 goals of the Declaration and another generation to achieve the Declaration's goals to reduce hunger and poverty. The Board thought that this transition could be achieved without extraordinary or still unavailable technologies or radical transformations of human societies. Now 15 years later, based on the progress and lack of progress (reported above) of the Millennium Development Goals, development seems on track for the 2050 sustainability transition, but environmental goals, especially those dealing with the oceans and atmosphere, are lagging far behind.

Great Transition of the GSG

In exploring the sustainability transition, the Board on Sustainable Development (BRC-BSD, 1999) undertook with the assistance of the Global Scenario Group, an analysis of the proposed Sustainability Transition, using for illustration, specific goals on hunger and the greenhouse gas emissions. It found that a sustainability transition is clearly possible, without requiring fundamental changes in technology or society, but it is 'just' possible. To move from business as usual without changing the economic system and people's lifestyles or values is daunting.

That analysis was an application of four widely used scenarios of future sustainability. The four, developed by the Global Scenario Group (Raskin, 2002), included a business as usual 'Market Forces' scenario, a 'Fortress World' scenario of defended haves and remaining have-nots, a possible but daunting 'Policy Reform' scenario, and a 'Great Transition' scenario that sought to achieve for all humankind "a rich quality of life, strong human ties and a resonant connection to nature." Such a transition envisaged major system change in environment, economy, and society and in the lifestyles and values held by people and institutions.

With almost two decades of hindsight, further research, and continuing experience, how likely is a Great Transition? In terms of needed values, a review of eight multinational surveys (Kates et al., 2006) of attitudes and behavior related to the three Great Transition values of quality of life, human solidarity, and ecological sensibility was undertaken. For the values of solidarity and ecological sensibility, there is widespread attitudinal support, although these strong beliefs are not necessarily reflected in the actual behavior of individuals, countries, or societies. Thus for these two goals of a Great Transition, it is bridging the gap between attitudes and behavior gap that is needed, not profound value change.

But the somewhat ambiguous quality of life values, including the rejection of material consumption beyond what is needed for a 'good life,' are not evident today, nor can large system changes be seen in major trends. There is widespread support for economic growth. A third of humanity continues to struggle with extreme scarcity, while another third is just beginning to aspire to an orgy of consumption. Indeed the greatest challenge of the Great Transition might be to create the growth and material conditions, while preserving the life support systems, that could eventually allow for the emergence of values of fulfillment and not wealth as the definition of well-being.

Sustainability Science

Sustainability science, as described by the journal, *Proceedings of the National Academy of Sciences* (PNAS) is: "…an emerging field of research dealing with the interactions between natural and social systems, and with how those interactions affect the challenge of sustainability: meeting the needs of present and future generations while substantially reducing poverty and conserving the planet's life support systems." The origins of sustainability science lie both in the grassroots efforts of scientists around the world and in the elite institutional efforts beginning with the National Research Council NRC-US Board of Sustainable Development.

A measure of the grassroots effort, as mentioned above, is in the 20 000 English-language scientific publications, with 37 000 authors who wrote articles between 1974 and 2010 that contained in their title, abstract, or key words 'sustainability' and/or 'sustainable development.' (Bettencourt and Kaur, 2011). Beginning in the 1990s, the number of authors of articles grows rapidly, doubling about every 8 years, and evidence a distinctive pattern of author locations and disciplines (**Figure 2**).

In more traditional sciences, authorship is concentrated in Japan, the United States, and Western Europe, but sustainability science authorship is much more widely distributed and includes significant numbers of authors from developing countries such as Kenya and Nigeria and almost all the emerging economies (Brazil, Russia, India, China, and South Africa). The authors' institutions include corporate laboratories, government and nongovernmental organizations, as well as universities large and small. Many of the papers originate in political capitals, such as Beijing, Canberra, London, Tokyo, and Washington rather than in academic centers.

Sustainability Science is also extraordinarily multidisciplinary, spanning the natural, social, and technological sciences. Using the disciplinary classification of the journals,

Figure 2 The graph illustrates the number of authors of English-language scientific publications, who wrote articles between 1974 and 2010 that contained in their title, abstract, or key words 'sustainability' and/or 'sustainable development.' Five key institutional and publication initiatives and field unifications are also shown by their approximate dates. Taken from Bettencourt, L.M.A., Kaur, J., 2011. The evolution and structure of sustainability science. Proceedings of the National Academy of Sciences 108, 19540–19545 with permission of PNAS.

a third of the papers were published in social science journals, a quarter in biological journals, and a fifth in engineering journals. In the judgment of Bettencourt and Kaur, sustainability science unifies around the year 2000, with most scholars and places connected with network links of co-authorship.

The elite institutional development of sustainability science is partly shown in Figure 2 as key institutional initiatives. Sustainable development emerged in the early 1980s from scientific perspectives on the interdependence of society and environment (ICSU, 1980). It entered the high political agenda through the publication by the Brundtland-led World Commission on Environment and Development (1983–87) report: *Our Common Future* and the subsequent United Nations Conference on Environment and Development held in Rio de Janeiro in 1992.

While a great political success, many scientists found it difficult both to conceptualize and measure sustainable development and make it a subject of scientific inquiry. To assist, the US National Academy of Sciences created a Board on Sustainable Development that began a 5-year effort to better connect science and technology to sustainable development including creating a sustainability science (NRC-BSD, 1999). Subsequent meetings of the World Academies of Sciences, the Initiative for Science and Technology for Sustainability (ISTS), the International Council for Science (ICSU), and the Third World Academy of Sciences in Japan, Sweden, Nigeria, Thailand, Germany, Canada, Chile, and Mexico embraced the notion of sustainability science (Clark et al., 2002), identified its core questions and methodologies, and launched sustainability science around the world (Kates et al., 2001). After the field unified around 2000, the PNAS, a major journal, started a section on sustainability science as one of its many disciplinary sections. By the end of 2012, 378 articles had been published in this unique section on sustainability science.

Both the grassroots and elite accounts find that sustainability science is a different kind of science that is primarily use-inspired as are agricultural and health sciences, with significant fundamental and applied knowledge components and commitment to moving such knowledge into societal action. From the grassroots effort it was clear that sustainability science was already in the air and in print prior to Board of Sustainable Development, but the elite international and regional scientific institutions saw that it needed theoretical and methodological framing beyond the topics of individual research. One such framing was the focus on socioenvironment interactions (also nature-society, socioecological, human environment interactions) and the search for core questions or research themes beyond the local or sectoral problems considered in most of the sustainability science literature. Major attempts to put together core questions (Kates et al., 2001) and thematic research (Levin and Clark, 2010) for sustainability science were made in 2000 and 2011. Combining these core questions and thematic research, there are seven major questions for research.

1. What shapes the long-term trends and transitions that provide the major directions for this century?
2. What determines the adaptability, vulnerability, resilience of human–environment systems?
3. How can theory and models be formulated that better account for the variation in human–environment interactions?
4. What are the principal tradeoffs between human well-being and the natural environment?
5. Can scientifically meaningful 'limits' be defined that would provide effective warning for human–environment systems?
6. How can society most effectively guide or manage human environment systems toward a sustainability transition?
7. How can the sustainability of alternative pathways of environment and development be evaluated?

Most recently, several proposed research frameworks (e.g., Dasgupta and Duraiappah, 2012; Arrow et al., 2012) have sought to make the Brundtland definition researchable and measurable by defining sustainable development as the well-being of people over the long run. Thus, society's development is sustained over a period of time if during that period intergenerational well-being does not decline. In Figure 3, human well-being (W) is an aggregate of various constituents such as material needs, health, education, opportunity, community, and security. These are a function of the goods and services that provide these constituents when consumed by people and in turn these are produced from a productive base composed of the assets: natural capital (Cn), human capital (Ch), manufactured capital (Cm), institutions and social capital (I), and knowledge (K). This productive base can then be considered to be the ultimate determinants of well-being, a relationship succinctly expressed as follows: W = +(Cn, Ch. Cm, I, K). This formulation suggests that assets of the productive base should have a worth or value to society. It has been shown that under an interesting range of conditions, this social worth of the productive base, aggregated as indices of 'inclusive wealth,' tracks the intergenerational well-being that can flow from it and thus serve as a conceptually grounded metric of sustainable development (e.g., UNU-IHDP and UNEP (2012); World Bank (2010)).

Sustainability Science is now at most two decades old, whether dated by the accelerated publication of the 1990s, the proposal by the National Academy of Sciences-Board on Sustainable Development in 1999, or as explicated in *Science* in

Figure 3 A research framework for sustainable development defined as long-run human well-being, i an aggregate of various constituents such as material needs, health, education, opportunity. community and security. These are a function of the goods and services that provide these constituents when consumed by people and in turn these are produced from a productive base composed of the assets: natural capital (Cn), human capital (Ch), manufactured capital (Cm), institutions and social capital (I), and knowledge (K) (drawn from Clark et al., forthcoming, with permission of the authors).

2001. Today the field has achieved an active solution-oriented research agenda, a theoretical perspective in coupled socio-environment systems, a large published library of new work (Kates, 2010), dedicated centers and institutes in many parts of the world, and a growing number of degree programs at every level. While sustainability science has become rooted in the scientific enterprise, it is being pursued somewhat differently in the US, the EU, Japan, and S. Africa. Its research questions are now better defined, but of the core questions and themes major, progress lags in half of them. Numerous degree programs have been created in colleges and universities, but common sets of needed competencies for students have not yet emerged. There are many examples of joint undertakings with practitioners from local communities, industry, government, and civil society, but fewer examples of solutions offered or problems solved. Thus the growing and exciting large body of research may be only slowly yielding solutions for the great environment and development challenges of this century.

Abstract

Revolutions in agricultural technology and policy throughout the twentieth century have dramatically changed farming practices. While these changes created necessary, short-term increases in food production, they also created environmental and social consequences that have called this agricultural system into question. Beginning in the 1960s, the environmental movement drew attention to the impacts of industrialized, chemical-intensive agricultural practices on the health of individuals and the planet. In addition, the consequences of agribusinesses on farmers and consumers throughout the world have sparked reactions against the injustices of a corporate, capitalist food system. These negative consequences of modern agriculture have shifted the discourse of agriculture and food security away from one of strictly growing more food to one of growing food in a way that is environmentally, socially, and economically sustainable.

Introduction

Throughout the process of industrialization and development, agriculture has been profoundly altered, disconnected from nature, and fit into the capitalist system of production (McMichael, 2000). Changes in food production resulted from technological, demographic, political, and economic changes, which increased yields, supported growing urban populations, affected domestic and international trade and trade laws, and grew lucrative, powerful agricultural businesses. Toward the end of the twentieth century, however, this system of agriculture was called into question as people perceived the negative environmental consequences, as well as the shortfalls of the system in meeting current and future demands.

By 2050, the projected increase in world population combined with increased meat consumption will require the world to produce twice as much grain as at the start of the twenty-first century (Tilman et al., 2002). This increased demand requires not only a sheer increase in production, but also a departure from the current system of agriculture, which has proved socially and environmentally unsustainable. The current methods of agricultural land use are "trading short-term increases in food production for long-term losses in ecosystem services, including many that are important to agriculture" (Foley et al., 2005, pp. 570–571).

The call for a more sustainable agricultural system came as a reaction to the numerous negative externalities associated with modern, industrialized agriculture. While 'sustainable agriculture' and 'sustainability' more generally are commonly used, they are quite recent in origin and variable in definition. Entering mainstream discourse after the 1987 UN World Commission on Environment and Development report, sustainable development, in general, was defined as "development that meets the needs of today without compromising ability of future generations to meet their own needs" (WCED, 1987). Sustainability has since been used to describe many different facets of development, including agriculture.

Although numerous definitions of sustainable agriculture exist, most agree on three basic, overlapping components: ecological, economic, and social sustainability (Jordan and Constance, 2008; Kaur, 2013; Pilgeram, 2013; Thompson, 2010). Environmentally, sustainable agriculture requires that the process of food production does not deplete natural resources faster or to a greater extent than they can replenish themselves. Second, to be sustainable within a capitalist economy, the food system must be profitable in the long-term for those involved in growing and consuming. Last, the facet of sustainability which receives comparatively little attention stresses the quality of life of farm workers and rural communities as well as the health and safety of consumers. These three dimensions of sustainability must each be addressed to meet the growing demand without compromising future generations' food access.

Agriculture in the Twentieth Century

During the twentieth century, agriculture has undergone changes that have dramatically altered the world's environment, landscape, and diet. Beginning with the shift from animal to machine plowing, and then from natural to chemical fertilizers and pesticides, and most recently with the advent of genetically modified seeds, revolutions in agricultural practices have created a food system disjointed from nature (Jordan and Constance, 2008; Kenney et al., 1991). While these shifts in agriculture accomplished a very necessary increase in yield to meet the demands of an increasing world population, they did so at the expense of the long-term capacity of our land, water, air, and traditional farming knowledge. In place of the formerly intimate connection between food and land, the ecosystem became something to alter and control to produce food as an "input in urban diets and industrial processing plants" (McMichael, 2000, p. 21).

Environmental

With 40% of the world's land area devoted to cropland and pastures, the modern system of intensive agriculture is one of the largest contributors to greenhouse gas emissions and is responsible for extensively altering the world's ecosystems (Foley et al., 2005). Modern farming often uses the practice of monocropping, alters the landscape, decreases biodiversity,

and relies on chemical fertilizers and pesticides that damage soil fertility, disrupt local ecosystems, and pollute runoff and ground water (Kaur, 2013). Animal grazing, which utilizes 25% of the world's land area, contributes to desertification, woody encroachment, and deforestation (Asner et al., 2004) as well as producing greenhouse gases. In addition to such land-related impacts of agriculture, crop irrigation accounts for 70% of fresh water extracted from underground (Thompson, 2010). These processes can in turn negatively affect future agriculture and population health by "diminishing the capacity of global ecosystems to sustain food production, maintain fresh water and forest resources, regulate climate and air quality, and mediate infectious diseases" (Foley et al., 2005, p. 572).

Due to the sheer scale of agriculture, its impact on the environment is crucial to consider. In addition, the demand for food is only increasing as the world population grows and diets shift to more resource-intensive foods. This increased need requires that the productivity of the land actually increases over time, and not merely remains constant. The focus on strictly growing more food in any way possible to combat hunger has lessened the productive capacity of our land and depleted or adulterated many water sources. To ensure food security for the growing population, the mind-set is shifting to prioritize for the way such increased production is accomplished and the long-term consequences of these practices (Lang and Barling, 2012).

Economic

In addition to the environmentally unsustainable aspects of modern agriculture, the technology-intensive system has created immense profits for large agriculture companies at the expense of farmers and consumers around the world. The initial infrastructure and technology for manufacturing chemical agricultural inputs in the United States came from chemical companies that had been manufacturing explosives during World War II. Following the War, these factories shifted to producing chemical agricultural inputs. A new form of agriculture and associated products were then exported throughout the world. Throughout the Cold War, the export of such technology, and the model of high-yield capitalist agriculture, to the developing world was encouraged and supported politically as an attempt to prevent more countries from falling into communism's orbit (Pilgeram, 2013).

As the twentieth century progressed, this industry bred high profit and powerful multinational corporations. These corporations, often termed "agribusinesses," are characterized by "large, industrial-type operations along the commercial food chain" (Walsh, 1975, p. 531). Agribusinesses have gone through numerous mergers, resulting in single companies such as Monsanto, which controls seed and chemical production and owns patents in the corn, cotton, and wheat sectors in multiple countries around the world. Between 1995 and 1998 alone, Monsanto spent over $8 billion buying seed companies (Shiva, 2000). The increase in size and scope of these corporations has increased corporate influence over international trade and intellectual property law, environmental policy, agricultural regulations, the chemical market, the media, and so on (Tokar, 2003). Such influence has disempowered farmers who are now dependent upon multinational corporations for expensive seeds and chemical inputs rather than on traditions of seed saving and natural forms of fertilizers and pesticides with significantly lower input costs. In addition, those purchasing food are subject to the potential risks associated with consuming highly processed products from chemical-intensive agricultural sources.

So, while economically advantageous for the companies themselves, the health of the environment, the quality of life of farmers, and the safety of consumers are all compromised on behalf of such profits. These profits are reaped strictly through the process by which the "world price for agricultural commodities strikingly divorced from cost" (McMichael, 2005, p. 271). The costs of producing and trading agricultural commodities are absorbed throughout the process by states, laborers, consumers, and unaccounted environmental degradation.

Social

As introduced above, the increase in necessary inputs has placed farmers in an economically difficult and disempowered situation; given the size and concentration of input corporations, farmers completely lack control over the price of inputs and, often, the selling price of crops. Farmers have become more vulnerable to price fluctuations as the world agricultural market has become increasingly integrated and the social structure of many countries has changed. Due to increased trade, many farmers shifted from subsistence farming or farming crops that could not compete with imports to producing crops they could sell on the international market. Shifting from diverse, subsistence farming to cash crop production encourages efficiency and specialization, which is often achieved through increasing farm size (i.e., economies of scale). This increase in farm size throughout the world consolidated land previously farmed by multiple small farmers, transforming subsistence and small, for-market farm owners into agricultural wage laborers. Unlike subsistence farmers and agricultural small holders, who frequently engage in a degree of subsistence farming, wage laborers must purchase all of their food, leaving them vulnerable to price fluctuations. In addition, many rural dwellers throughout the world, through either the push of farm consolidation or the pull of industrial development in cities, moved to urban areas and became entirely dependent on wages to acquire food. The increase of trade, combined with a decrease in farmers, has created a growing population of consumers dependent on the international food market for their food security, often with negative consequences on their food security (Walton and Seddon, 1994).

In addition to these products and technologies that augment the natural biological growing cycle, more recent innovations in agricultural input attempt to fit agricultural production into the capitalist, highly industrial production mold. From a capitalist standpoint, "the problem with agriculture, then is how to make nature step to the tune of the capitalist clock, that is how to revolutionize the biological processes themselves, not just how to use machinery or fertilizer to augment natural processes" (MacLennon and Walker, 1980, p. 28). These attempts to fit farming into an industrial

model, when successful, have contributed to a loss of traditional knowledge about sustainable farming practices that have existed for the history of agriculture (Barndt, 1997).

Origins

This move toward unsustainable development practices, especially in the realm of food production and the environment, gained popular attention in the 1960s. Rachel Carson's book *Silent Spring*, published in 1962, is often cited as the beginning of the modern environmental movement in the United States. This book raised awareness regarding the negative side-effects of chemical pesticides on the environment, particularly the impact of DDT on bird populations. In the years since *Silent Spring*, environmental concern has grown into a global movement, embedded in domestic and international policies, governmental organizations, and NGOs. The term 'sustainable development' and subsequent sustainability agendas followed in 1987, when the UN explicitly addressed the issue of sustainability in its report 'Our Common Future.' Agriculture became a major component of these environmental and sustainability movements, as critics argued that despite the gains in output, "when all its hidden costs are considered, modern industrial agriculture is not the bargain it appears to be" (Beus and Dunlap, 1990, p. 591). With the growing awareness of the environmental consequences of agriculture, the perspective on global food security also shifted. Initially, the approach to fighting world hunger was to grow more food by whichever means possible, but by the first decade of the twenty-first century, the influence of the sustainability discourse and new challenges to food security broadened and reshaped critiques of the food and agricultural systems (Lang and Barling, 2012). The current criticisms and modifications of the modern agricultural system stress sustainability across the different dimensions of agriculture and food access including environmental, economic, and social considerations.

As the sustainable agriculture paradigm diverged from that of conventional agriculture, some key differences emerged in critiques and prescriptions. According to Beus and Dunlap (1990), these key differences between conventional and alternative agriculture fall, respectively, into six major categories: centralization/decentralization, dependence/independence, competition/community, domination/harmony with nature, specialization/diversity, and exploitation/restraint. Within each of these categories, alternative or sustainable agricultural practice stresses smaller-scale, resource-conserving practices that value local communities.

What is Sustainable Agriculture?

Various parties engaged in sustainable agriculture define it in different ways, ranging from slight modifications needed within the existing structure, to drastic overhaul of power relations that currently govern food production. At its broadest, following the UN definition, sustainable agriculture is a method for growing food that does not compromise the future of food production. Most authors extend this definition, similarly to Beus and Dunlap, by defining sustainable agriculture in opposition to conventional agricultural practices. Carried further, sustainable agriculture is sometimes viewed as a complete rejection of locating agriculture with the corporate, capitalist system. Despite the range of possible definitions of sustainable agriculture, most facets of the process fall into one of three major categories: environmental/ecological, economic, and social sustainability.

Ecological

Those components that come to mind when one thinks of sustainability are likely related to the health of ecosystems and the environment. Impact studies and enacted sustainable programs and practices address different aspects of environmental consequences depending on the geographic location and the type of food production, from organic fertilizers to nonpolluting fish farming, the scope of ecological changes is enormous. Generally, the mind-set stresses organic practices over blind faith in technology to mimic traditional farming methods and natural ecosystem processes as much as possible. To accomplish this, sustainable agriculture proponents have called for reduced dependence on external, nonrenewable energy sources, recommending a shift to renewable and local resources for energy and farm inputs. This theme of decreasing the scale of dependence as much as possible occurs often in sustainability discourse, beginning at the level of the farm. Creating closed loop farming requires practices such as crop rotation, composting, combined livestock and crop production, diversified plant types and species, water collection systems, and sun or wind-power harvesting. For those inputs which a farm is not able to self-produce, local production is prioritized, favoring small-scale community-based production to dependence on centralized corporations. This stress on local production extends to sale and consumption. In contrast to the existing system, which "produces food for long storage and transportation times using vertically integrated processes of production and distribution, increasingly large corporate farms, and heavy use of pesticide and other chemicals" (Gasteyer et al., 2008, p. 48), local consumption requires less transport time, and therefore a decreased need for preservation in the form of chemicals or climate control.

Economic

The economic aspects of sustainable agriculture vary in purpose and form more than those devoted to protecting the environment, as practices that are economically advantageous for corporations may not benefit consumers, those beneficial for farmers may hurt corporate profits, and so on. Within discourse on sustainable agriculture, however, certain themes emerge regarding the economic direction in which agriculture should move. In general, sustainable agriculture entails a move toward smaller-scale, less capital- and technology-intensive production. In this production, farmers and other food-system actors are called to consider the external costs and long-term economic outcomes of present-day actions rather than strictly immediate monetary costs and short-term profits. In addition to farm specific economic concerns, much sustainability discourse encourages a move away from materialism more generally to valuing the

nonmonetary dimensions of nature. Whereas some economic analyses of sustainability attempt to monitor long-term, externalized costs to the environment by calculating the future profit losses or monetizing the negative impacts on the environment, others instead encourage valuing nature and the environment for its own sake, rather than fitting it into the man-made capitalist framework of costs and profits.

Social

The final category of agricultural sustainability addresses issues of social and economic equity in the current food system. This dimension of sustainability questions whether food can be deemed sustainable if, while not endangering the environment or future farm solvency, still creates or depends upon inequality and exploitation for production. Thus, models of sustainable agriculture feature decentralized control and value local communities. Decentralization of agricultural production means more farms and farmers, as well as local and regional processing and sales (Beus and Dunlap, 1990). This decentralized structure reduces the capacity of the food system to hide the costs "in the poverty of migrant and third world agricultural workers" (Cone and Myhre, 2000, p. 188). Through buying food directly from farmers and abstaining from purchasing food grown or processed by distant, transnational corporations, consumers become more informed regarding the food production process, often purchasing food from farms or farmers' markets directly. This direct interaction between farmer and consumer removes some potential for hidden short-term costs and exploitation of farmers, by allowing the consumer to interact with the farmer and have access to the farm where food is grown.

A criticism sometimes waged against the sustainable agriculture movement, however, is its primary market of privileged consumers (Pilgeram, 2011). If the concept of sustainable agriculture is used to represent an ideal or a crucial aspect of development, then one cannot solely focus on the effects on the environment and on wealthy, first-world consumers. Such critics argue that to be properly sustainable, the food system must ensure access to nutritious, affordable food for the world's population, and not only for a privileged few.

Sustainable Agriculture in Practice

One form of sustainable agriculture that has gained momentum in the United States is Community Supported Agriculture (CSA). CSA exemplifies the ways environmental, economic, and social aspects of sustainable agriculture can be carried out. Ecologically, CSAs are organic, ecologically diverse farms often located near urban consumers. To provide a range of food products to members of the CSA, farmers must grow many types of food on the same farm, allowing for easier crop rotation practices than on specialized farms. Economically and socially, this system seeks to restructure food production by operating through collective ownership and planned production. In CSAs, members purchase 'shares' at the beginning of a season, which provides initial, necessary capital for farmers to buy production inputs for the growing season. In addition to this preliminary capital influx, farmers also have a guaranteed income for the season regardless of market fluctuations or crop failure. Producers and consumers share risks associated with farming and receive weekly shares of food according to what and how much was harvested that week. Members of CSAs believe agriculture is "unable to survive in an economy dominated by the market, in which prices radically fluctuate, the cost of land escalates, and resources—natural and human—are exploited" (Cone and Myhre, 2000, p. 188). Unlike other forms of supporting local agriculture, such as farmers' markets, this form of local, sustainable agriculture movements seeks not only to support environmentally sustainable forms of agricultural production, but also to radically restructure the way people view and participate in the economic structure of food production and consumption.

Future of Food

While sustainable agriculture has made substantial gains over the past few decades in terms of awareness, research, policy, and producer and consumer behaviors, much more is needed in all components before we have a just and sustainable global food system. The health of ecosystems, society, and individuals is highly influenced by our food production process. Ensuring safe, long-term food access for the world's growing population is a defining challenge of our time, and whether we can effectively address it will dictate future development of our society.

Abstract

Following the UNCED conference in Rio 1992, the concept of sustainable development has developed into a new model of societal development institutionalized in a large number of international programs and agreements. While the concept itself is widely accepted as a normative guiding principle, fundamental differences appear at the implementation level. The debate on sustainable development thus can be analyzed as a controversially structured, politically contested field of discourse. This article reconstructs both the hegemonic version of sustainable development as 'sustainable growth' and the various counterdiscourses, which – in the North as in the South – refer back to either a stronger ecocentric understanding of nature or put the model of global industrial growth and development as such into question.

Even though the concept of sustainability has been long anchored in the context of forestry, the much more comprehensive idea of sustainable development first entered the international policy debate via the Brundtland Commission report 'Our Common Future' (WCED, 1987) and the subsequent United Nations Conference on Environment and Development (UNCED) in Rio de Janeiro in 1992. The concept of sustainable development has been significantly shaped by the institutional context of the United Nations and refers to previous UN debates, reports, commissions, conferences, and declarations. Within this context, the focus is firstly on *global* problems, and secondly on the goals and action strategies which take the welfare of *humanity as a whole* into consideration. Facing threatened ecological conditions of human development, this aim had already been served some years before by the creation of the United Nations Environment Program at the UN Conference on Human Environment in Stockholm 1972 and the elaboration of the 'World Conservation Strategy' by the International Union for Conservation of Nature. In the early 1980s, two UN commissions had also addressed the growing poverty gap between North and South, dealing with the lack of social and economic development in most developing countries (Brandt, 1980).

Both lines of discussion initially remained largely unconnected, however, because environmental issues constituted a high priority for the industrialized countries while for the southern countries, the development issue stood in the foreground. In addition, environmental issues were negotiated at that time in terms of 'Limits to Growth' (Meadows et al., 1972), which created fundamental conflicts between environmental and development interests. Against this background, the World Commission on Environment and Development (WCED), headed by Gro Harlem Brundtland, was expected to merge the controversial lines of discussion. With the concept 'sustainable development,' the commission appeared to have found the magic formula needed to integrate environmental and social issues into a productive vision of development.

The Hegemonic Sustainability Discourse

What is the core of this concept? The fundamental idea on which the WCED report and the documents of the subsequent UNCED Conference in Rio is based (Rio Declaration, Agenda 21) is the vision of a global development of mankind that allows the needs of all people, present as well as future, to be met. This anthropocentric vision refers to the normative principles of both intra- and intergenerational fairness. It aims to integrate environmental, social, and economic dimensions of development and to translate them into verifiable objectives and measures with the aid of a broad participation of society. It calls for "harmony among human beings and between humanity and nature" (WCED, 1987: 65) and it is supported by an optimistic belief in the feasibility of this vision.

Although the WCED report discusses key problems, their interconnections, and possible solutions (population and human resources, food security, species and ecosystems, energy and development, sustainable industrial development, the urban challenge), it is not a scientific but rather a political document. It attempts to bridge the existing controversies between the commission members, their divergent interests, and interpretation of problems. It therefore remains vague in many respects. But it is precisely this vagueness that allows for a broad consensus.

The question is *how*, by which kind of framing, the WCED report and the Rio documents succeed to bridge the contradiction between global environmental and developmental interests. This 'reconciliation' is accomplished in two argumentative steps (Dingler, 2003: 222f.). The first is the transformation of 'sustainability' from a concept focused on resource conservation to a concept focused on the satisfaction of basic human needs, including the needs of future generations. The second transformation step is to no longer view economic growth as a 'limit' but as a prerequisite for sustainable development. Because the negative environmental consequences of industrialization and economic growth are understood as a result "of the present state of technology and social organization on environmental resources" and not as a result of growth per se (WCED, 1987: 8), and, at the same time, the solution to poverty is seen in economic development, it is technology and social organizations that have to be improved. The solution to global environmental and developmental problems, therefore, would not be in the absence of growth, but in a new era of reinforced, ecologically sound '*sustainable growth.*' As a means to promote this goal (1) an

increase in efficiency, (2) dematerialization, and (3) a rational, global management of resources are recommended (Dingler, 2003: 227).

The Rio Conference takes up this conceptual reframing of sustainability. In the 'Agenda 21,' a comprehensive action plan for the twenty-first century, the emphasis is on making the production and consumption patterns of the North more sustainable. In addition to increasing efficiency and the demand for new, environmentally sound technologies, the importance of science for rational resource management is particularly emphasized, thus significantly enhancing the scientific nature of the discourse on sustainable development. In addition, Agenda 21 is concentrating on environmental economic instruments of trade liberalization and the opening of markets, which promotes the economic reformulation of the concept of sustainability into categories of economic, environmental, and human 'capital.' Through this, the discourse on development policy with its focus on poverty and basic needs, which still dominated the Brundtland report, was tacitly transformed into a *discourse of ecological modernization of economic growth*. Sustainable development in the South then means the transfer of 'green' growth patterns from the industrialized countries to developing countries.

This hegemonic conceptual framing of sustainability is accompanied, however, by another, procedural element: the emphasis on the *participatory* nature of searching for and trying out new paths of sustainable development. In particular, the action plan put forth by Agenda 21 has provided socially and ecologically engaged groups and organizations all over the world a new legitimation for participation in planning processes and the collaborative search for sustainable solutions to local problems.

Meanwhile, this hegemonic variant of the sustainability discourse has been included in many policy areas of Western countries. Local Agenda 21 processes have initiated a multitude of sustainability projects. New approaches to sustainable production and consumption were tested by businesses and committed consumers, and have evolved in some cases, e.g., in the field of organic food consumption, to absolute trendsetters. At the international level, following the Rio conference, a veritable marathon of negotiations and conferences emerged to bring about mandatory international regimes into the areas of climate, biodiversity, forests, fisheries, water conservation, toxic waste transports, etc. (cf Winter, 2006).

Counterdiscourses on Sustainable Development

The hegemonic understanding of sustainable development, however, encountered considerable criticism in southern as well as in northern countries. This criticism can be assigned to two lines of discourses (cf Banerjee, 2003; Dingler, 2003; Dryzek, 1997; Escobar, 1995; Milton, 1996; Sachs, 1999): a first counterdiscourse that follows a different understanding of nature (1) and a second counterdiscourse that follows a different understanding of development and growth (2).

All three positions, the hegemonic discourse and its criticisms, as well as the various subthreads of the debate, can be graphically located in a field of discourses on sustainable development that can be spanned along two axes (see **Figure 1**)

- along a horizontal axis of divergent images of nature and technology with the opposing poles 'techno-centrism' (technical-industrial model of progress) versus 'eco-centrism' (embedding society in the web of nature), and
- along a vertical axis of divergent models of economy and societal organization with the opposing poles 'world-market model of industrial growth' versus 'models of local self-sufficiency and self-determination.'

Nature-Related Counterdiscourses

As part of the hegemonic discourse of sustainability, the preservation of ecosystems and natural resources is of instrumental character; it serves the sustainable satisfaction of human needs. According to this view, the development of human needs is not subject to any absolute natural barriers, but only to (rectifiable) social and technical limitations. This typical modern discourse on industrial progress is put into question from two positions: (1) from radical ecologists who reject the anthropocentric premise of the sustainability discourse and postulate that nature has its own, intrinsic values that must be respected; (2) from a neo-Malthusian understanding of 'limits to growth' which postulates that the limited carrying capacity of the Earth may be exceeded only at the cost of collapse.

Radical Ecology

'Radical ecologists' (Eckersley, 1992; Merchant, 1992) conceive human society not as the center, but only as one element of a larger living community whose natural elements, animals, plants, ecosystems, landscapes, the planet as a whole, have the same rights for development as humans (see Dryzek, 1997: 155 ff.). Throughout the past century this concept of man and nature was one of the basic motives of conservation and environmental movements. It formed its romantic and spiritual pole whose other pole was represented by a rational, utilitarian concept of sustainable resource management (cf Hays, 1959; Nash, 1967). In the US context, ecocentric positions are closely linked to 'deep ecology,' 'ecofeminism,' and 'bioregionalist' models of social life.

Deep ecology (cf Devall and Session, 1985; Naess, 1973) disengages itself from environmental policy approaches that would only like to reform industrial society in some technical or economic aspects. Deep ecology is concerned with more fundamental changes. "Its two basic principles are self-realization and biocentric equality. Self-realization means identification with a larger organic 'self,' beyond the individual person. […] The idea is to cultivate a deep consciousness of organic unity, of the holistic nature of the ecological webs in which every individual is enmeshed. […]. Biocentric equality means that no species, including the human species, is regarded as more valuable or in any sense higher than other species" (Dryzek, 1997: 156).

Ecofeminism (cf Diamond and Orenstein, 1990; Plumwood, 1993) "covers a broad set of ideas, analyses, and action forms that have evolved since the 1970s in the context of women's activism in the environmental and peace movements in the North and South. These approaches are interconnected by looking for common causes of natural exploitation and discrimination of women and the goal of linking

Figure 1 The field of discourses on sustainable development.

environmental policy to the empowerment of women" (Vinz, 2005: 7). Vinz distinguishes between two schools of thought within ecofeminism, 'cultural' and 'social' ecofeminism. While the latter examines the social recoding of nature and gender with the development of modern science, giving way to a new exploitation of nature and oppression of women, the former plays a more central role in radical ecology. This cultural variant suggests a "special closeness of females to nature due to bodily (menstruation, childbirth) and spiritual reasons"; female-specific values (feelings, empathy, corporeality) – in contrast to an instrumental, male approach to nature – are seen as the "guarantor for a respectful relationship with nature and for a life in peace" (Vinz, 2005: 7).

Bioregionalists (cf Sale, 1985) share, together with cultural ecofeminism, the practical, anti-industrial utopia of agricultural self-sufficiency and reruralization. They also propagate small, decentralized settlements, adapted to their natural environments, which should enable people to live in 'ecological balance' with the surrounding nature.

In densely industrialized and urbanized countries these are scarcely feasible options for action, however. Ecocentric positions, therefore, are frequently expressed as direct action protest in diverse fields of conflict like transportation, agriculture, or energy policy. Not only the foundation of new radical ecological organizations like Greenpeace (1971), the Sea Shepherd Conservation Society (1979), or Earth First! (1979), but also the direct actions of animal rights activists or opponents of green genetic engineering are all fed by the unconditional moral impetus of the 'defense' of the maltreated nature, whether animals, landscapes, or people.

Limits to Growth

Biologists, environmental scientists, and environmental activists usually share the idea that human society is only one subsystem of nature. Human use of natural resources is part of the overall dynamics of planetary ecosystems. This is analyzed in categories of material and energy flows as well as in categories of the Earth's human carrying capacity. According to the 'limits to growth' approach, both the resource availability and the sink function of planetary ecosystems then have clear natural boundaries that limit economic growth (Daly, 1996). Whereas this discourse is compatible with various reformist top-down and bottom-up strategies, the prominent neo-Malthusian discourse of 'Survivalism,' advocated by Hardin, Ehrlich, and Meadows et al., relies on radical, hierarchical control strategies that are to limit both population and economic growth (Dryzek, 1997: 23ff.). The need for such a strict control strategy is justified by the argument that humankind has already overshot the Earth's carrying capacity by far. This argument is impressively underlined by exponential growth curves, global computer models, and dire predictions about the consequences of the impending ecological collapse.

Criticism of the Conventional Concepts of Development and Growth

This counterdiscourse includes a broad range of critical positions. The most prominent of them are (1) the anti-imperialist discourse of small farmers and indigenous people in the South, (2) a complementary Northern critique of consumerism, and (3) the Marxist critique of social and ecological exploitation by the dynamics of capitalist accumulation.

Sustainable Development as a Neocolonial Strategy

From this perspective, the hegemonic strategy of sustainable development is marginalizing subsistence-based ways of life of small farmers and indigenous peoples in the South. The central criticism is that the industrial model of 'sustainable growth' follows a neocolonial pattern of 'development' that accelerates the destruction of smallholder agriculture close to nature only under new, ecological auspices (Escobar, 1995; Mies and Shiva, 1993; Sachs, 1999). Linked to this is the criticism of the hegemonic model of Western rationality that devalues local knowledge and uses it only instrumentally as a patentable resource for pharmaceutical purposes. The winners of this model of sustainable development seem to be multinational companies, national governments, and the urban consumer class who all profit from 'green' innovative technologies and from 'sustainable growth.' The losers are the approximately 2 billion people who depend on land, forests, and water as their traditional means of livelihood.

The conventional notion of progress and development, therefore, should be fundamentally questioned. Local rural protest movements are thus seen as supporters of emancipatory visions, fighting not only for a decentralized control over natural resources and habitats, but also for the recognition of cultural diversity. The myth of the 'primitive ecological wisdom' of indigenous and traditional peoples who lived across many generations in 'harmony with nature' and as responsible guardians of environmental resources links this local community discourse with the discourse of radical ecologists (Milton, 1996).

Sufficiency and Degrowth Discourse

In the industrialized countries of the North, a complementary criticism of the hegemonic sustainability discourse is found. It is based on the normative principle of ecological justice as well as on a new concept of 'good life.' Given the social inequalities and the ecologically disastrous consequences of global economic growth, the proponents of this position plead for both the dismantling of global industrial dependencies and the restraint of consumption in the North. New models of prosperity have to be developed which follow a 'cosmopolitan localism' and are guided by principles like "living well instead of possessing much" (Sachs, 1999; Sachs et al., 1998). Among economists, this vision has been discussed for some years now under the label 'degrowth' (Jackson, 2009; Latouche, 2009). The central argument is first that the possibility of dematerializing economic growth and decoupling it from energy consumption (not only in relative but also in absolute terms) is an illusion, and second that an increase in material goods above a certain level by no means increases the subjective well-being, but only leads to additional burdens and dependencies. The aim is, therefore, to strengthen regional economies and to achieve a new balance between self-sufficiency and market economy. Instead of consumerism, life has to be refocused on the idea of 'modest wealth' (Latouche, 2009).

Green Marxism/Critical Political Ecology

This position generally assumes that local and global environmental problems are an inherent part of a capitalist economy that is pushed forward by a limitless need for capital valorization and accumulation. This implies both social exploitation and the exploitation of nature. Thus, capitalism is not only responsible for repeated social and economic crises, but it also increasingly undermines the natural conditions of human life. Nevertheless, the possibilities of regulating the ecological crisis are considered controversial in the eco-Marxist debate. For some, the exacerbation of global environmental problems are regarded as a new frontier of capitalism (Altvater, 2005; Clark and York, 2005; O'Connor, 1988), while others see in the Rio model of 'sustainable growth,' at least a possibility for regulating the ecological crisis (Brand and Wissen, 2012; Peet et al., 2011). This, however, does not solve the inherent exploitative character of capitalism. Rather, the sustainability concept is seen as an ideological, depoliticizing concept that interprets global environmental problems as a common and 'external' threat to all mankind, while it conceals the existing power relationships and inequalities in the reconstruction of a 'green capitalism' (Swyngedouw, 1997).

The program of 'sustainable growth' thus has been strongly questioned from different positions. The resulting conflicts, however, were significantly mitigated by the participatory character of the sustainability process inspired by Rio. On the one hand, this increased the importance of Non Governmental Organizations in the various fields of global environmental governance. On the other, this also led, on the local and national level, to the flourishing of new forms of citizen participation, dialogical forms of politics, and cooperative networks to promote sustainable development. This vivid field of activities, in nationally varying forms, also included representatives of critical positions (for the German case see Brand, 2011).

Perspectives of Sustainable Development

The first wave of sustainability initiatives that were carried by the 'spirit of Rio' waned at the beginning of the new century. New topics began to dominate the international agenda. Although the dramatic warnings about the catastrophic consequences of climate change remained a key issue in the media, '9/11,' the 'war on terrorism,' and the deep financial and economic crisis that swept the Western world since 2008 have changed political priorities. In this context the concept of 'green economy,' a new political focus on 'low-carbon technologies,' and renewable energies, seemed to be an adequate answer both to global economic and environmental problems. It provides a new magic formula "that embodies the promise of a new development paradigm, whose application has the potential to ensure the preservation of the earth's ecosystem along new economic growth pathways while contributing at the same time to poverty reduction" (UN DESA, 2011: v). Considering

the dependence of profound changes in the human relationship to nature to equally fundamental changes in the structural organization of societies, it is unlikely, however, that an economic conversion to green technologies per se will achieve the desired general solution to global environmental and poverty problems (Brand, 2012: 30f.). As ecological transformation and issues of global justice are inseparably linked with each other a wider, integrative concept of sustainable development will remain on the agenda in the foreseeable future.

Abstract

This article reviews the emergence of sustainable development, considers the problems attached to it, and argues that a critical and holistic understanding of sustainable development in which the environmental, economic, cultural, and social are deeply interwoven may be one potential pathway for social work to contribute to the human and nonhuman world.

Introduction

The aim of this article is to define sustainable development in a way that is useful to social workers in their teaching, study, and practice. Using the conventional definition of sustainable development as its starting point, the authors argue that this is both too limited, and in its universality too unspecific, to be meaningful. They draw attention to the indivisibility of the social, environmental, and economic, as well as the cultural, in the ways in which we live, the ways in which our natural and social world has become unsustainable, and therefore the ways in which we need to address this unsustainability. Each of these characteristics (the first three of which are sometimes called 'pillars' or 'legs of a stool') imbues the others, so that one cannot understand the economic without understanding how it is socially, culturally, and naturally re/produced. In effect, each gives us a perspective, or a starting point, but only inasmuch as it enables us to understand the whole.

Having established the common definition, the authors review the evidence that suggests that its promise has not materialized and that even where local, small-scale sustainability appears to have been achieved, this is compromised by the outsourcing of pollution and resource exploitation needed to achieve sustainability in a single place. The authors argue, then, by introducing notions of environmental justice and injustice, that nothing short of global sustainable development is fair, both internationally and intranationally. The authors consider how the sustainable development agenda is being replaced in ways that they consider to be both positive (through considerations of well-being) and more problematic (for example, through resilience). They consider a number of examples that point to both the opportunities and challenges for sustainable development, foremost among which is climate change.

Following this more general discussion, the authors identify how social workers need to engage with sustainable development, from being explicit as to how environmental problems negatively affect the people and groups who social workers work with, and how an holistic approach to social, economic, and environmental problems is likely to have a positive impact on social work service users. Ultimately, the authors argue, a failure to holistically attend to the problems that create unsustainable development will affect social workers, social service providers, users, and carers, which in turn makes the case for social workers to be aware of, and active in, working toward a more sustainable environment.

Definition

The term sustainable development has come into common usage since *Our Common Future* was published in 1987. This was prepared by the World Commission on Environment and Development (WCED), a United Nations–sponsored enquiry into how the world community could negotiate an environmentally, socially, and economically sustainable future with costs and benefits shared between rich and poor countries. While this definition coined by the WCED (also known as the Brundtland Commission after its chairperson, Gro Harlem Brundtland) has become well rehearsed, it is also much misused, and often misunderstood:

> Sustainable development is development that meets the needs of the present without compromising the ability of future generations to meet their own needs. It contains within it two key concepts:
>
> - the concept of 'needs,' in particular the essential needs of the world's poor, to which overriding priority should be given; and
> - the idea of limitations imposed by the state of technology and social organization on the environment's ability to meet present and future needs. (WCED, 1987: p. 43)

As Erik Swyngedouw has commented, sustainable development is supported by everyone, from Greenpeace to Bill Gates and the labor unions (2007). The WCED's definition was a compromise necessitated by a group of policy makers from countries across the rich and poor worlds. While much of the rich West demanded selective restrictions on growth to protect rapidly degrading environments, more powerful poorer countries such as Brazil, Malaysia, and Indonesia challenged these demands on the grounds that their capacity to develop their economies would be compromised. Sustainable development, then, was a compromise, and a compromised concept, which promoted the need for economic growth, while acknowledging that this should not come at the expense of environmental and social degradation. Others argue that sustainable development provides a discursive justification for 'ecological modernization,' or development inflected with a pale green tinge of bike paths and biofuels, but that does not fundamentally challenge development trajectories or balances of power (Krueger and Gibbs, 2007; Pepper, 1996).

The Performance

Almost 30 years after this definition was published, the world is far less sustainable than it was in 1987. Sustainable development comprised one of the United Nations Millennium Goals, set out in 2000, with clear targets to be achieved by 2015. The United Nations acknowledges that there is scant chance for Goal 7, to ensure environmental sustainability, to be met, with the only achievement appearing to be successful being to halve the proportion of people without sustainable access to safe drinking water.

The world has also seen significant changes since 1987, which have affected its ability to achieve sustainable development: the fall of the Berlin Wall following the collapse of the centrally planned economies of the USSR and central and eastern Europe; the first Gulf War fought over oil resources in the Middle East; the invasions of Afghanistan and Iraq (arguably as much motivated by the energy security fears of the United States and the United Kingdom, as by other security issues); the rise of the new economies of Brazil, Russia, India, and China whose energy and resource needs pose a significant threat to environmental sustainability, and which change the balance of power worldwide; the concomitant precarity of Western economies, which are still attached to traditional growth models; and the advance of global warming evidenced by temperature rises, retreating glaciers and ice caps, and increasingly turbulent weather. Add to this, the apparent inability of rich countries to reduce their resource consumption, while also failing to contribute as much as they initially agreed to funding poor countries' attempts to better manage their environments, and the widening gulf between the richest and the poorest, and it is clear that sustainable development has been, at the global scale, a chimera. The attachment of international organizations and individual states to an economic accounting system measured by gross domestic product (GDP) developed in the wake of the Second World War to stimulate production, is outdated and ill-equipped to address contemporary problems, such as climate change (Waring, 1988).

Scale

In order to achieve sustainable development globally, there also needs to be action at national and subnational levels and it is here that social work could take a central role. The articulation of this interrelationship by the 'Think Global, Act Local' entreaty has inspired many local communities and governments to tackle unsustainable practices, where these are under their control, yet social work – particularly in the Global North – has been slow to actively engage with these possibilities. The individualized nature of social work practice has shifted focus away from the creative possibilities offered through global/local initiatives even when change could potentially be within their grasp. While some localities have been imaginative and energetic in pursuing this, as evidenced by various alliances (for example, International Council for Local Environmental Initiatives, Local Governments for Sustainability), including some that have made significant achievements (such as through the Transition Towns movement), social work has broadly failed to engage with these social and community development movements.

One reason for this is the continued emphasis on economic growth driving government policies worldwide, which severely compromises the ability of both local governments and social work departments to follow policies and practices that prioritize social and environmental sustainability. There is now a groundswell of opinion from a number of prominent economists, among others, that historic economic growth models are themselves unsustainable, and increasingly unable to deliver economic sustainability, let alone able to foster environmental and social sustainability. For example, Nicholas Stern, former Chief Economist at the World Bank, has argued in a major report for the UK Treasury for the precautionary principle to guide legislation on climate change (Stern, 2006), while Joseph Stiglitz, another former Chief Economist at the World Bank, and who won the Nobel Memorial Prize in Economic Sciences in 2001, reported in 2009 for a Commission set up by the then President of France, Nicolas Sarkozy, that economies could not sustain continual growth at the expense of the environmental and social damage they were doing internationally as well as within countries (Stiglitz et al., 2009). Also in 2009, Tim Jackson published a report for the United Kingdom's Sustainable Development Commission, which was highly critical of economic growth, and advocated an alternative model of 'Prosperity without Growth' in order to achieve environmental and social, as well as economic, sustainability. Given that most rich countries have, despite a reliance on traditional economic growth models, experienced economic recession since these reports have been published emphasizes that these models do not have the capacity to deliver sustainable development.

Within social work in the Global North, neoliberal approaches to national development have promoted an increasingly individualized approach to social work practice. Casework has come to dominate service provision, resulting in neglect of opportunities for community development and action. This highlights both the need for, and the challenge of, adopting a global perspective on sustainable development. The individualized notion of practice results in the impact of environmental issues tending to be addressed superficially through the experiences of one family, individual, or service user group rather than through the explicit recognition of the interconnectedness of the modern world. To overcome this, a global perspective on sustainable development is required for a number of reasons. First, without this, it would be possible for individual countries (or towns, cities, or regions) to claim sustainability internally, while contracting out their unsustainable practices (from exporting polluting industries to countries with cheaper labor costs or lower health and safety regulations, to moving vulnerable populations to poorer areas with cheaper housing costs). This only accentuates the divide between rich, 'clean,' 'sustainable' areas and poor, 'dirty,' 'unsustainable' ones. On this basis, sustainability (the goal of sustainable development) can only be achieved globally, and until then it is likely that sustainable development in one area is contingent on unsustainable development somewhere else, directly contradicting the social justice principles on which social work is based. Second, given the highly internationalized nature of industry (from oil and gas to finance), some form of

global governance is necessary to prevent multinational companies from exploiting differences in sustainable development legislation to continue unsustainable practices, rather than to change the ways in which they produce goods and do business. This highlights the need for social work both to develop an international voice, as advocated by the International Federation of Social Workers (IFSW) (2013), and to engage politically with arenas traditionally deemed outside the social work 'remit' (see how this is being developed in article Global Agenda for Social Work and Social Development).

Well-Being

There is increasing emphasis from academics from various disciplines across the social sciences, think tanks, and nongovernmental organizations, on alternative concepts to 'growth,' which are focusing on 'well-being' (Jackson, 2009; NEF, 2009). The decoupling of economic wealth from well-being has been identified as the 'Easterlin paradox' (Easterlin, 1974) after work undertaken by the American economist who identified that as a society gains in economic wealth this is not necessarily reflected by a rise in happiness, relative to other countries (NEF, 2009). This is likely to be aggravated in societies that privilege economic growth above any other kind of development, such as the United States and the United Kingdom, but will not characterize countries such as Bhutan (ranking 141 of 187 on the 'World Development Index' measured by the United Nations Development Programme Human Development Indicators), which consistently comes top of world rankings of happiness. In 1971, Bhutan decided to measure its wealth not by GDP, but by gross national happiness, which measures "the quality of a country in a more holistic way [than GDP] and believes that the beneficial development of human society takes place when material and spiritual development occurs side by side to complement and reinforce each other" (Ura et al., 2012: pp. 6–7). Bhutan's achievements, which prioritize environmental conservation and sustainability, include a doubling of life expectancy over 20 years, enrolling almost 100% of its children in primary school, and an overhaul of its infrastructure. By doing so, it offers the international community an alternative set of values and aspirations, and a mechanism to measure these. The irony is, however, that their ability to achieve these is compromised by global environmental degradation, which affects water resources and pollution across the Himalayan region, over which Bhutan has no control (Kelly, 2012).

Research undertaken by NEF (2009) identifies the aspects that people interviewed across Europe attribute to their own happiness and well-being. In this, well-being is categorized into personal and social attributes, such as a satisfying life, vitality, resilience and self-esteem, positive functioning, supportive relationships, trust and belonging, and well-being at work. Not only did this identify countries whose populations experience higher states of well-being (Scandinavian countries, led by Denmark, and Switzerland did better on both measures; Central and Eastern European countries did worst), but also highlighted intranational differences. For example, across Europe, certain circumstances indicate stronger or weaker well-being. Being a woman, belonging to an ethnic minority group, living with children, being ill or disabled, and being unemployed (but not retired, which had a positive correlation with well-being) were all negatively associated with well-being. While this may not be particularly surprising to social workers from across the globe whose daily work is to engage with the impacts of these subjective inequities, it highlights the role that social workers can play in these newly emerging debates.

These attributes suggest that the reach of the original definition of sustainable development is neither wide nor specific enough to capture all dimensions of people's lives. Moreover, a further dimension – a fourth 'leg' of the sustainability 'stool' – has been proposed by the United Nations Educational, Scientific and Cultural Organization's World Commission on Culture and Development so that cultural policies become a key part of sustainable development (Leach, 1998).

Climate Change

Just how ineffective sustainable development has been to date is evident from the global approach toward climate change. While identified as long ago as 1896, climate change first reached international prominence outside specialist circles in 1992 when the United Nations Conference on Environment and Development held in Rio de Janeiro drafted a climate change protocol whose purpose would be to hold or return global CO_2 emissions to 1990 levels. This would be achieved primarily by Annex 1 (rich) countries, which, once having signed up to the protocol, would develop their own climate change reduction strategies. The Kyoto Protocol, so named for the city of its launching, was initiated in 1997, and eventually came into force when the required number of signatories had been achieved in 2005. Russia and Australia signed at this point, although the world's largest CO_2 emitter, the United States, never endorsed the protocol. This was a mere 7 years before it was due to expire in 2012, and the questions of how to replace it, and which countries should be included in its renegotiation, have vexed annual climate change conferences since (notably Copenhagen in 2009). For further details on Kyoto and its successors, see the United Nations Framework Convention on Climate Change Web site. Of particular note, and germane to the discussion of sustainable development here, is the gradual and almost imperceptible change of the discourse around climate change, from 'mitigation' (preventing the conditions that create climate change) to 'adaptation' (adapting to a climate changed world). This has invoked a shift from creating 'sustainable development,' which might suggest some changes to the ways in which resources are transformed, used, consumed, and disposed of, to 'resilience,' which implies changes in the ability of people, communities, and/or countries to cope with the effects of climate change, be these increased flooding, changes in food supply, or patterns of disease. However, resilience (and capability, which enables people or communities to become resilient) is limited by lack of basic resources, as Amartya Sen has noted in his body of work over many years (see, for example, Sen, 1999). People who are poorly sheltered, hungry, or malnourished, who are illiterate

and/or poorly educated, are least able to withstand environmental problems. Moreover, these conditions disproportionately expose them to environmental problems such as pollution, which in turn affects their capacity for resilience. This not only affects people in poor countries but also is a recognized challenge for social work across both the Global North and the Global South.

Environmental In/Justice

The WCED definition of sustainable development extends the issue of intergenerational equity to a concern that "must logically be extended to equity within each generation" (Chapter 2, point 3). It continues:

> A world in which poverty and inequity are endemic will always be prone to ecological and other crises. Sustainable development requires meeting the basic needs of all and extending to all the opportunity to satisfy their aspirations for a better life.
>
> Living standards that go beyond the basic minimum are sustainable only if consumption standards everywhere have regard for long-term sustainability. (Chapter 2, points 4 and 5)

While there is an assumption that this intragenerational equity needs to be achieved between rich and poor countries, it is also important to note that current intragenerational inequalities persist within the richest countries (see, for example, Wilkinson and Pickett, 2009).

Even in times of expanding GDP, wealth does not 'trickle down' from the wealthiest to the poorest within the richest nations. Despite continuous rises in GDP in the United Kingdom and the United States, both countries have increasing levels of wealth inequality (Reuters, 2012). According to Reuters, using the Gini coefficient (where 0 equals perfect parity and 1 represents all wealth going to a single person), inequality in income distribution in the United States has risen in each of the past two decades. Between 1989 and 2011, the index rose 6% nationally, to its highest level since the US census started measuring it in the 1960s. Using census data to compare average income, the top 5% of income earners on average earned 24 times as much as the bottom 20% in 1989. By 2011, that ratio was 28 to 1 (Reuters, 2012). According to Danny Dorling, in 2012, the richest 1% of people in the United Kingdom took home 15% of all income, compared to 6% in 1979, higher than at any time since 1940 (Dorling, 2012). Wilkinson and Pickett (2009) have identified how greater income inequality correlates with higher rates of crime and mental illness, with countries such as the United States and Portugal, and the United States, the United Kingdom, and Australia dominating these respectively.

The concept of the 'Fourth World' was introduced by George Manuel, the founding president of the World Council of Indian Peoples, in the mid-1970s, initially to describe people effectively disenfranchised within their own countries, such as the native North Americans or the Australian aboriginal people (Manuel and Posluns, 1974). The concept has now expanded to include stateless people, and people in both rich and poor countries who are significantly impoverished. Manuel Castells (1998: p. 164) defined the Fourth World as the "multiple black holes of social exclusion" regardless of the wealth of the countries in which these black holes exist, from the slums of Mumbai, rural areas of Latin America, or US inner city ghettos.

This represents a huge challenge for sustainable development in general and social work in particular, and is a social indication of collective failure to engage effectively with the processes necessary to achieve sustainable development. People inhabiting this Fourth World are not 'resilient' to environmental problems which, when they occur, are more likely to impact them more harshly than others. Consider, for example, the victims of aggravated natural weather events such as Hurricane Katrina, which affected the poor and black communities of New Orleans much more than those with savings, insurance, and private mobility (Cutter et al., 2006). The environmental in/justice literature also suggests that the most marginalized of populations are more likely to be exposed to environmental problems than the less marginalized, whether it is because they can only afford housing in the poorest, most polluted neighborhoods, or lack the education, expertise, and connections to fight off polluting activities (see, for example, Bullard, 1999; Kurtz, 2007; Pulido, 1996; Taylor, 2000). Over and above the effect that poverty has on the sustainability of people's lives, race and ethnicity have been found to be disproportionately related to environmental problems (Agyeman, 2013). Gender is less well-recognized in the environmental justice literature, but nonetheless it is clear that being female also disproportionately exposes women, on average, to more environmental problems than men (Buckingham and Kulcur, 2009).

Meanwhile, excesses of consumption are becoming lethal; obesity, a disease of the rich West, is diminishing life expectancy. High consumption of meat products not only compromises health, but also affects the amount of land available to grow food for direct human consumption. Hunger/malnutrition and the inability to feed one's own family are the most fundamental attacks on human autonomy and dignity. And yet, even in the United Kingdom, the world's sixth richest economy (as reported by the Centre for Economics and Business Research in December 2012), a new informal measure of deprivation is the rise of the food bank, with an estimated 200 000 people using food banks in 2012, up from 26 000 in 2008/2009 (Trussell Trust, 2012).

Sustainable Transitions

Among the dispiriting reading about the lack of progress on achieving sustainable development from and between the local to the global scales, there are inspiring projects that address sustainability jointly from economic, environmental, social, and cultural perspectives.

The 'Coriander Club' women's community gardening project in East London, supported by the Women's Environmental Network, illustrates well how women from marginalized Bangladeshi households in East London have been supported with help in transforming common areas within and between council flat buildings. The Bangladeshi community is one of the poorest and most marginalized in the United

Kingdom (Bernard and Turner, 2011). Many are refugees from the 1972 war of independence fought by Bangladesh, and originated in a rural area in which Muslim women experienced living in purdah, did not earn independent incomes, and were largely illiterate. In the United Kingdom, Bangladeshi people have some of the poorest employment prospects, and women continue to be isolated, and more likely to suffer physical and mental ill health than women from other ethnic groups. Meanwhile, their families tend to be larger. Growing their own fruit and vegetables not only enabled these women's families to eat more healthily, but also empowered the women, reducing their isolation and improved a derelict urban neighborhood (Rycroft, 2000).

Local food gardening projects are small but significant ways of achieving greater economic, environmental, social, and cultural sustainability in cities. Such projects can create greater neighborhood cohesion, and offer opportunities for people isolated from the communities in which they live to develop social bonds, which in turn can lead to better physical and mental well-being. As well as refreshing or providing new skills, enabling families to eat more healthily on restricted incomes, and to grow their own food, community gardening reduces the amount of food that is transported unfeasibly long distances. Urban gardening programs have flourished in many cities across North America, in Detroit (see the history of the Detroit Angels who helped recover derelict space at Detroit Urban Sustainability Web site, the link for which is provided below), and notably New York City, although their hold on land here is tenuous, given the pressures on land for housing and other commercial development (Englander, 2001).

Sustainable Development and Social Work

Social work is slowly waking up to the role of the environment in practice. Despite a number of authors campaigning for the recognition of the natural world within social work since the early 1990s (see Gray and Coates, 2012 for an excellent summary), it is only more recently that the debates have begun to really take hold. The IFSW now calls on social workers to "recognise the importance of the natural and built environment to the social environment" and "to develop environmental responsibility and care for the environment in social work practice" (IFSW, 2012). However, research has indicated that social workers in the United States, for example, are no more environmentally aware than members of the general population (Shaw, 2013). Conversely, in Cuba, young social workers are known as 'doctors of the soul,' who recognize the imbrication of the social, economic, and environmental. For instance, in 2006, they visited homes replacing incandescent light bulbs with free energy-saving compact fluorescent bulbs as part of Cuba's 'energy revolution,' and have also been involved in a program to replace household appliances such as fridges and televisions with new energy-efficient models (see the Direct Action Web site listed below).

To date, discussion of social work's potential relationship with the environment has been from two standpoints: first, that social work as a profession needs to think about the natural world as it impacts on humans (environmental justice); second, that the environment is in fact inseparable from the social world and therefore the understanding of the human, social, and natural are inherently intertwined (ecological justice). As summarized by Miller et al. (2012: p. 271), "In environmental justice theories, humans remain the metaphorical sun around which questions of natural resources orbit. In ecological justice theories, nature or Earth expands in scope to become the universe, with recognition that humans are one part of that universe." For social work, the differentiating factor between these two standpoints is an ethical one – as effectively summarized by Gray and Coates (2012): Should one think of sustainable development as being sustainable human development or should social workers also take nonhuman interests into account?

Yet, there is also a moral dimension to the debate that connects with discussions of power, socioeconomic systems, and political structures. It asks us to reflect on not just the interconnectedness of the well-being of the planet and the well-being of humankind (Dominelli, 2012: p. 199) but to connect this socioecological perspective with the critical tradition in social work (Peeters, 2012). In other words, to understand how the exploitation of the Earth's resources is unequally controlled as a direct result of current neoliberal structures and processes. To address this, this dimension of the discussion highlights that social work needs to draw on its critical tradition through working with social movements to build capacity at the local level to resist change as well as advocate for policy change at the governmental level (Peeters, 2012). From this perspective, the indivisibility of the Earth's and people's well-being (Dominelli, 2012: p. 199) further strengthens the argument for the need to bring an end to the 'market-based free-for-all' that not only has prevented poverty eradication but has resulted in preventing equal access to the world's resources (Dominelli, 2012: p. 197).

To date, however, it is sustainable human development that has clearly dominated both social work theory and practice. This can be illustrated by one of the central theoretical approaches to social work practice, the ecological approach, of which the person-in-environment model (Bronfenbrenner, 1979) has come to dominate. This model focuses almost entirely on the social environment which, as Dominelli (2012: p. 3) notes, tends to "ignore power relations based on geo-political social structures that have a deleterious impact upon the quality of life of poor and marginalized populations and the Earth's flora and fauna." This indicates a weakness within the current rights-based approach to social work practice. This can clearly be seen in contemporary notions of social justice as these fail to recognize that social justice can only ever be achieved if environmental justice is also ensured. Therefore, there is an immediate need to expand current understanding of rights to include environmental rights whereby the disproportionate impact of environmental degradation on marginalized or poor communities is explicitly acknowledged. As noted above, there is also an underlying ethical argument, in which social work should also start to challenge itself to move beyond the current human-centered approach to practice through expanding the social work universe so that both human and nonhuman become incorporated into practice models. What the authors have tried to argue throughout this article is that the holistic understanding of sustainable

development in which the environmental, economic, social, and cultural are deeply interwoven highlighted here may be one potential pathway for social work to begin to contribute to this expanded – and sustainable – universe.

Sustainable Development: An Economic Perspective

Edward B Barbier and Joanne C Burgess, University of Wyoming, Laramie, WY, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Sustainable development is concerned with meeting the needs of the present without compromising the ability of future generations to meet their own needs. Recent advances in three areas of the sustainable development literature are ecosystem services and resilience; environmental Kuznets curves and environment–growth relationships; and technological innovation, endogenous growth, and resource dependency. Progress toward sustainable development requires measuring the social, ecological, and economic impact of declining natural resources; improving our estimates of the costs of depleting natural capital; establishing appropriate incentives, institutions, and investments for sustainable management of natural capital; and encouraging interdisciplinary collaboration.

In the late 1980s, the World Commission on Environment and Development, otherwise known as the Brundtland Commission, defined sustainable development as "development that meets the needs of the present without compromising the ability of future generations to meet their own needs" (WCED, 1987). Since then, sustainable development has received significant attention from the global community at the local, national, and international level amid concerns about climate change, biodiversity loss, tropical deforestation, ecological degradation, and other environmental depletion and degradation problems.

This article provides a broad definition of sustainable development and discusses its various interpretations. Recent advances in three areas of the sustainable development literature are ecosystem services and resilience; environmental Kuznets curve (EKC); and technological innovation, endogenous growth, and resource dependency. For each area, the basic concept is explained and the implications for sustainable development are discussed. Finally, four key policy options for achieving sustainable development are identified: measuring the ecological, social, and economic impacts of declining natural resources; improving our estimates of the economic costs of depleting natural capital; establishing appropriate incentives, institutions, and investments for sustainable management of natural capital; and encouraging interdisciplinary collaboration between the relevant social and behavioral sciences undertaking research on sustainable development.

Concept of Sustainable Development

Definition of Sustainable Development

The broad concept of sustainable development encompasses considerations of equity across and within generations, taking a longer-term perspective, and accounting for the value of the environment in decision-making (Pearce et al., 1989). This interpretation is easily translated into normative terms: an increase in well-being today should not have as its consequences a reduction in well-being tomorrow. That is, future generations should be entitled to at least the same level of social and economic opportunities – and thus, at least the same level of economic welfare – as currently available to present generations. Consequently, economic development today must ensure that future generations are left no worse off than present generations. Or, as some have succinctly put it, per capita welfare should not be declining over time (Arrow et al., 2012; Pezzey, 1989).

Stated in this way, the objective of 'sustainability' is different from that of the standard economic goal of 'efficiency' (Bishop, 1993). That is, there are potentially an infinite number of development paths for an economy, only some of which are sustainable. Efficiency, therefore, does not guarantee sustainability, as some efficient paths are not sustainable. At the same time, there is no reason why an economy could not be both efficient and sustainable.

Consequently, sustainable development continues to receive increasing international recognition, and it has become a key guiding principle for the global society (Barbier and Markandya, 2012; National Research Council, 1999; UNU-IHDP-UNEP, 2012).

Total Capital Stock

The above interpretations of sustainable development also imply that it is the *total* stock of capital employed by the economic system, including natural capital, which determines the full range of social and economic opportunities, and thus well-being, available to both present and future generations. Society must decide how best to use its total capital stock today to increase current economic activities and welfare and how much it needs to save or even accumulate for tomorrow, and ultimately, for the well-being of future generations.

However, it is not simply the aggregate stock of capital in the economy that may matter but also its composition, in particular whether present generations are using up one form of capital to meet the needs of today. For example, much of the interest in sustainable development has risen out of concern that current economic development may be leading to rapid accumulation of reproducible and human capital, or *human-made capital*, but at the expense of excessive depletion and degradation of *natural capital*. The major concern has been that by depleting the world's stock of natural wealth irreversibly, the development path chosen today will have detrimental implications for the well-being of future generations. In other words, according to this view, current economic development is essentially unsustainable.

Some economists argue that the more critical issue of debate is not whether natural capital is being irreversibly depleted

but what are the costs of these losses and can society today compensate future generations for the current loss of natural capital. For example, as Pearce et al. (1989: p. 3) state, "future generations should be compensated for reductions in the endowments of resources brought about by the actions of present generations." A key question is in what form should this compensation take place? On this issue, opinions diverge. This difference of view is often referred to as *weak sustainability* versus *strong sustainability* perspectives.

Weak and Strong Sustainability

Two distinct interpretations of sustainable development are referred to commonly in the literature as 'weak' and 'strong' sustainability (Barbier and Markandya, 2012; Barbier et al., 1994; Neumayer, 2010; Turner, 1993). According to the *weak sustainability* view, there is no inherent difference between natural and other forms of capital, and hence the same compensation rules ought to apply to both. As long as the natural capital that is being depleted is replaced with even more valuable, reproducible, and human capital, then the value of the aggregate stock – comprising human, reproducible, and the remaining natural capital – is increasing over time. Maintaining and enhancing the total stock of all capital alone is sufficient to attain sustainable development.

In contrast, proponents of the *strong sustainability* view argue that reproducible or human capital cannot substitute for all the environmental resources comprising the natural capital stock or all of the ecological services performed by nature. Consequently, the strong sustainability viewpoint questions whether human, reproducible, and natural capital comprise a single homogeneous total capital stock. Instead, proponents of strong sustainability maintain that some forms of natural capital are *essential* to human welfare, particularly key ecosystem goods and services, unique environments and natural habitats, and even irreplaceable natural resource attributes such as biodiversity. Uncertainty over the true value to human welfare of these important assets, in particular the value that future generations may place on them if they become increasingly scarce, further limits our ability to determine whether we can adequately compensate future generations for irreversible losses in such essential natural capital today. Thus, the strong sustainability view suggests that environmental resources and ecological goods and services that are essential for human welfare and cannot be easily *substituted* by human and reproducible capital should be protected and not depleted. The only satisfactory compensation rule for protecting the welfare of future generations is to keep essential natural capital intact. That is, maintaining or increasing the value of the total capital stock over time in turn requires keeping the nonsubstitutable and essential components of natural capital constant over time.

Aspects of Sustainable Development

Ecosystem Services and Resilience

The multiple benefits arising from natural ecosystems have become increasingly critical to many conservation and development decisions worldwide. It is increasingly common to refer to these multiple benefits as *ecosystem services*. Or, as the Millennium Ecosystem Assessment (2005) defines them, "ecosystem services are the benefits people obtain from ecosystems."

The growing literature on ecological services also implies that ecosystems are assets that produce a flow of beneficial goods and services over time (Barbier, 2011; Daily et al., 2000; Dasgupts, 2008). For example, as Daily et al. (2000: p. 395) state, "the world's ecosystems are capital assets. If properly managed, they yield a flow of vital services, including the production of goods (such as seafood and timber), life-support processes (such as pollination and water purification), and life-fulfilling conditions (such as beauty and serenity)." In principle, then, ecosystems should be treated as in other form of wealth in the economy, and by accounting for their contribution to current and future economic well-being, we would have a better measure of economic progress.

If ecosystems are also considered capital assets – or *ecological capital* for short – then efforts to attain sustainable development should account for the contributions of ecosystems as well. However, as Dasgupta (2008: p. 3) reminds us, "ecosystems are capital assets" that "differ from reproducible capital in three ways: (1) depreciation of natural capital is frequently irreversible (or at best the systems take a long time to recover), (2) except in a very limited sense, it isn't possible to replace a depleted or degraded ecosystem by a new one, and (3) ecosystems can collapse abruptly, without much prior warning."

There is mounting evidence that under pressure from external disturbances, ecosystems may switch abruptly to a contrasting alternative stable state, or *ecological regime* (Folke et al., 2004; Holling, 1986; Levin and Lubchenco, 2008; Scheffer et al., 2001). Although a variety of disturbances may trigger the regime shift, what determines whether an ecosystem will change to an alternative state depends on its *resilience* or *robustness* – the ecosystem's ability to absorb large shocks or sustained disturbances and still maintain internal integrity and functioning.

The loss of ecosystem functioning and resilience will lead to a decline in the availability of some economically important biological resources and ecological services. For example, the loss of fish stocks as the result of pollution impacting on marine systems, the inability of rangeland pastoral systems to recover from drought, and the decline of the watershed protection function of degraded forests. At first, these ecological and welfare impacts may be localized, but if they occur on a sufficiently large scale, they may generate wider national, regional, or even global effects such as climate change (*see* Climate Change: Economics). Although the scale of such impacts and their ultimate effects on human welfare are often uncertain and difficult to determine, the irreversible loss of key biological resources and ecological 'services' through the disruption and breakdown of ecosystems could constitute a growing problem of *ecological scarcity* (Barbier, 1989, 2011). The rising 'scarcity' of ecological resources and services will mean that they will increase in value relative to human-made goods and services produced in economic systems. Moreover, persistent and rising ecological scarcity may be an indicator of more widespread and frequent disruptions to the functioning and resilience of ecosystems and increases the likelihood of ecological collapse and catastrophe on ever-widening scales (Folke et al., 2004; Levin and Lubchenco, 2008; Scheffer et al., 2001).

Implications of Ecological Functioning and Resilience for Sustainable Development

Given the rate at which ecological disruption is occurring globally as a result of the cumulative impacts of pollution, habitat modification, and conversion and overexploitation of some biological resources, the ecological functioning and resilience upon which many important ecological resources and services depend may be undermined. Thus, not only is there a danger of depleting essential ecological components of natural capital but the widespread disruptions to the functioning and resilience of ecosystems may mean that these essential components are being lost irreversibly. Therefore, the ecological economics literature generally endorses the strong sustainability view.

Ensuring sustainable development first will require identifying those essential ecological resources and services that are most at risk from current patterns of economic activity and development. Second, it is necessary to take appropriate policy measures to protect the irreplaceable components of natural capital. Finally, it is important to maintain the functioning and resilience of the key ecosystems on which they depend. This implies a fundamental rethinking in the way in which countries currently manage their environments, as well as the relative importance of policies for environmental protection in the process of economic development. The additional costs that are required to adjust current patterns of economic activity and development could be significant, especially in the short and medium term, and may constrain such a comprehensive shift in policy.

EKC and the Environment–Growth Debate

There has been a long-standing debate about the relationship between economic growth and the environment. An early view was expressed in the publication of the Club of Rome's *Limits to Growth* in 1972 that there exists a *trade-off* between economic growth (measured by rising real per capita incomes) and the environment, whereby an improvement in one implies a reduction in the other (Meadows et al., 1972; Daly, 1987). The modern sustainable development debate has focused more on the potential *complementarity* between growth and the environment, where growth is considered compatible with improved environmental quality (see Pearce et al., 1989; Barbier and Markandya, 2012).

An extension to this literature looks at the analysis of EKC. This is the hypothesis that there exists an 'inverted U'-shaped relationship between a variety of indicators of environmental pollution or resource depletion and the level of per capita income (Kuznets, 1955; Grossman and Kreuger, 1995; Shafik, 1994; Stern et al., 1996). The implication of this hypothesis is that environmental degradation should be observed to increase initially, but to eventually decline, as per capita income increases. To some extent, this combines the two previous views on the relationship between economic growth and the environment. That is, at low incomes, there exists a trade-off between economic growth and environmental quality, while at higher incomes, economic growth is complementary to improved environmental quality.

These studies suggest that EKC relationships are more likely to hold for only a few pollutants with short-term and local impacts such as sulfur dioxide (SO_2) and to a lesser extent solid particulate matter. In addition, even when an EKC relationship is estimated, the 'turning point' on the curve, where environmental degradation starts to decline with per capita income, is very high relative to the current per capita GDP levels of most countries. This is a particular problem for less developed countries with low per capita income levels (*see* Environment and Development). However, several recent studies have also demonstrated that EKCs are highly susceptible to structural economic shifts and technological changes, which are in turn influenced by policy initiatives such as the Montreal Protocol and the Second Sulfur Protocol.

Implications of EKCs for Sustainable Development

Some commentators have argued that the empirical evidence of EKCs supports the general proposition that the solution to combating environmental damage is economic growth itself (Beckerman, 1992). For example, the EKC literature offers limited evidence that for certain environmental problems, particularly air pollutants with localized or short-term effects, there is an eventual reduction in emissions associated with higher per capita income levels, which may be attributable to the 'abatement effect,' which arises as countries become richer (Panayotou, 1997). Also, both the willingness and the ability of political jurisdictions to engage in and enforce improved environmental regulations, to increase public spending on environmental research and development, or even to engage in multilateral agreements to reduce emissions may also increase with per capita income levels.

Other commentators have been more cautious, noting that conclusive evidence of an EKC relationship applies only to a few pollutants, which makes it difficult to support more general growth–environment linkages. It has also been noted that even for those pollutants displaying EKC characteristics, aggregate global emissions are projected to rise over time, demonstrating that the existence of an EKC relationship for such pollutants does not imply necessarily that, at the global level, any associated environmental damage is likely to disappear with economic growth. Therefore, the EKC literature should not be taken to imply that economic growth on its own will foster environmental improvement automatically. As Panayotou (1997) concluded, "when all effects are considered, the relationship between growth and the environment turns out to be much more complex with wide scope for active policy intervention to bring about more desirable, and in the presence of market failures, more efficient economic and environmental outcomes." Or, as Arrow et al. (1995) have succinctly put it, "economic growth is not a panacea for environmental quality; indeed it is not even the main issue."

Endogenous Growth, Technological Innovation, and Resource Dependency

Other literature with important implications for sustainable development looks at *endogenous growth*, *technical innovation*, and *resource dependency*. A key feature of endogenous growth models is that technological innovation, that is, the development of new technological ideas or designs, is *endogenously*

determined by private and public sector choices within the economic system (hence the term 'endogenous' growth) rather than outside (i.e., 'exogenous') the system (Romer, 1990). This implies that the level of technology in an 'endogenous growth' economy can be advanced perpetually through public and private investments such as research and development expenditures and increases in human capital skills. Since *technical innovation* adds to physical capital already used in production, the economy can potentially 'sustain' growth rates indefinitely. Furthermore, as the economy develops, its growth rate should eventually diminish until it reaches its long-run growth rate (Barro and Sala-I-Martin, 2004).

This debate over the role of innovation in economic growth has led to empirical studies across countries and regions in the factors underlying long-term economic growth. Empirical evidence seems to support the notion that rich countries have higher rates of savings or more 'effective' institutions and implies that persistently bad government policies and ineffective institutions are inhibiting the long-run growth prospects of low-income countries. In addition, poor countries may fail to achieve higher rates of growth because they fail to generate or use new technological ideas to reap greater economic opportunities.

Institutional and policy failures in poor economies are important determinants of their inability to innovate sufficiently to achieve higher long-term growth rates. Another important factor may be the structural economic dependence of these economies on their natural resource endowments. Explanations as to why *resource dependence* may be a factor in influencing economic growth point to a number of possible fundamental linkages between environment, innovation, and long-term growth relevant to poor economies. Previous studies of an economy's dependence on natural resources and its long-run growth (Dasgupta and Heal, 1979; Stiglitz, 1974) have been extended by Barbier (1999) to include an endogenous-growth economy in order to determine whether an economy's dependence on an exhaustible natural resource is necessarily a binding constraint on long-term growth. The results of the analysis show that sufficient allocation of human capital to innovation will ensure that in the long-run resource exhaustion can be postponed indefinitely, and the possibility exists for sustained long-term per capita consumption. However, when negative feedback effects between the rate of resource utilization and innovation exist, the conditions under which it is possible to sustain per capita consumption over the long run are much more stringent and again assume that the economy is able to build up sufficient human capital and to innovate.

Implications of Endogenous Growth Theory, Technical Innovation, and Resource Dependency for Sustainable Development

Endogenous growth theory offers some support for the weak sustainability view. That is, provided that obstacles such as persistent policy distortions, political instability, and institutional failures can be overcome, any economy – even a low-income and resource-dependent developing country – should be able to foster endogenous innovation to substitute human and physical capital for a declining natural capital base in order to sustain economic opportunities and welfare indefinitely. The key appears to be developing effective policies and institutions, including the necessary public and private investments to enhance research and development and human capital skills.

Unfortunately, in most low-income countries current economic policies and investments in agriculture, forestry, and other resource-based sectors have led to rapid changes – frequently with adverse economic consequences – in resource stocks and patterns of use. Demographic trends have often worsened the relationship between population and resource-carrying capacity in many regions, and chronic environmental degradation may itself be contributing to social conflict and political instability, thus undermining the social and economic conditions necessary to foster long-term innovation and development (Homer-Dixon, 1995). In addition, the type of 'resource-saving' innovations envisioned in most endogenous growth models is likely to be technologies to abate pollution and other waste products and to conserve the use of raw material and energy inputs. However, many ecological resources and services, such as biodiversity, amenity services, and ecological functions, are less amenable to substitution by the conventional resource-saving innovations developed in the economic process. Thus, innovations are less likely to lead to opportunities for the substitution of the more unique, and possibly essential, range of ecological resources and services, including the general life-support functioning and resilience of ecosystems.

Policy Issues and Options for Sustainable Development

This section discusses the policy issues and options for sustainable development. There are some important areas of common ground for policy makers that make good progress toward sustainable development, regardless of the viewpoint on strong and weak sustainability. For example, as there exists considerable scope for substituting human and physical capital for natural capital through conservation and substitution of resource inputs, reducing pollution, and improving environmental protection, then designing policies for sustainable development must begin with these basic objectives in mind. To do this requires progress in four areas.

First, it is important to improve existing efforts to measure the economic, social, and ecological consequences of natural capital depletion and degradation. That is, in order to consider how well an economy is substituting physical and human capital for natural capital, it is necessary to measure how much the value of the natural capital stock has been 'depreciated' through current efforts to use environmental resources and services to promote greater levels of consumption and investment in the economy. Determining the 'sustainable' level of income and consumption, that is, accounting for the increases in the total available goods and services in the economy *net* of the depreciation in the value of the natural capital stock, is an important economic approach to measuring sustainability. Equally, determining the ecological 'limits' to exploitation of the natural capital stock, including ecological thresholds; carrying capacities; and key ecological goods, services, and

natural environments that might be considered 'essential,' is important ecological contribution to measuring sustainability.

Second, many of the resources and services of our natural capital endowment are either 'unpriced,' meaning that unlike other goods and services in our economy there are no markets for them, or 'underpriced,' meaning that where markets do exist for some environmental goods and services, the prices in these markets do not necessarily reflect their true contribution to human welfare. As long as environmental goods and services continue to be 'unpriced' and 'underpriced,' then their contribution to human welfare relative to other goods and services in the economy is effectively 'undervalued.' Thus, in order to promote more effective policies for sustainable development, it is necessary to adequately capture the economic values for environmental goods and services and to develop suitable tools for assessing these values.

Third, determining an appropriate 'mix' of human, reproducible, and natural capital to ensure sustainable development is ultimately about designing appropriate incentives, institutions, and investments for efficient and sustainable management of the natural environment. In order to promote sustainable development, it is important to determine the causes of environmental degradation, particularly where the failures of institutions, markets, and government policy are the main contributing factors, and to demonstrate how correcting these failures can lead to improved incentives and investments for efficient and sustainable management of natural capital (*see* Environmental Policy: Protection and Regulation).

Finally, in order to make genuine progress toward sustainable development, it is necessary to foster collaboration across the social and natural sciences, such as economics and ecology, to attain the common goal of sustainable development.

Sustainable Lifestyles

Stewart Barr, College of Life and Environmental Sciences, University of Exeter, Exeter, UK

Abstract

Sustainable lifestyles is a widely recognized but often contested description of the ways in which citizens/consumers conduct conscious or habitual practices that have a benefit to the local or global environment. Often utilized as a policy instrument, the term has been applied widely in countries like the United Kingdom through top-down behavioral change programs. The understanding of sustainable lifestyles as a tool for governing the environment, therefore, is critical to an appreciation of how states seek to deploy environmental policy through engaging what we will call citizen/consumers. The outworking of these policy goals is manifested in a range of approaches to encouraging sustainable living, such as individual contributions to energy saving, water conservation, environmentally friendly travel practices, and sustainable waste management. Indeed, the range of practices we can describe as 'sustainable' is also reflected in the variety of intellectual approaches within academic research, focusing on the psychological, sociological, and pragmatic components of behavioral change. This article will explore these approaches in turn, arguing that the challenge for social science is to provide a more ambitious vision of what a sustainable lifestyle might look like, which draws more on the social than the individual as a frame of reference.

Introduction

Writing an article about such a common term as 'sustainable lifestyles' might seem one of the simpler tasks for an author in an encyclopedia on social and behavioral sciences, yet this broad term is one that comprises a range of definitional, political, and intellectual challenges. Even if the notion of sustainability is put to one side for a moment, the term itself is one that comes with a great deal of political baggage because of the ways in which nation-states, particularly in Western capitalist economies, have attempted to draw more and more upon behavioral change as a mechanism for delivering policy goals formerly ascribed to the central state. There are important questions that arise about why individuals have become the focus of policy making on the environment and why, given the challenge posed by anthropogenic climate change, it should be individuals who bear the responsibility for tackling carbon emissions. Indeed, these often poorly addressed questions are frequently accompanied by a simplistic view of behavioral change, and thus sustainable lifestyles, through modes of policy making and communication that fail to draw on the considerable intellectual insights gained from the social and behavioral sciences. Psychology has added much to our understanding of so-called proenvironmental behavior since the late 1960s and has recently been joined by sociology, bringing insights into the contextual and situated nature of sustainable lifestyles. Indeed, one consequence of the increased policy attention being focused on behavior change is the emergence of a further strand of research (largely an extension of the psychological approach), which places emphasis on pragmatic change programs in community settings.

These intellectual contributions mean that an academic understanding of sustainable lifestyles is complex and that the translation of academic research into policy making can often be problematic, given the epistemological assumptions underlying much of the research within different disciplines. Such research is often focused on contemporary framings of environmental issues, like anthropogenic climate change, and perhaps lacks the ambitiousness of research that asks a much needed set of questions about proactive social transformation in the light of environmental change, rather than mitigative and reactionary approaches. Indeed, the intellectual trajectory of research on the notion of sustainable lifestyles has largely been a Western pursuit, dominated by a discourse of maintaining current standards of living and economic growth, and disenfranchising other (and perhaps innovative) ways of living sustainably that have emerged in developing world contexts. This article therefore explores these key themes and challenges, focusing initially on the political framing of sustainable lifestyles, before examining the three major intellectual approaches in detail and concluding with a discussion on the future of research in the field.

Governing Sustainable Lifestyles

A brief look back in history (and quite recent history at that) reveals that our current approach to understanding and promoting environmental action is quite different from that deployed in the early years of the environmental crisis. Roberts (2011) notes how the first decade of significant environmental political debate (the 1970s) was dominated by international negotiations and a broad acceptance that global environmental problems were to be dealt with by state action through regulation and legislation. In this era of the 'big state,' governments often owned many national assets like industrial plants and large quantities of land, and were able to exercise considerable influence, frequently underlined by a strong belief that the state was best placed to deal with global problems like environmental pollution. We might rightly ask the question, therefore, of how it is the case that the predominant policy mechanism for tackling global issues like anthropogenic climate change in the twenty-first century is not state intervention, large-scale regulation or a command and control economy, but rather a reliance on citizens, as consumers, to effect the changes required.

 http://dx.doi.org/10.1016/B978-0-08-097086-8.91052-3

The answer may be found in the underlying political and economic conditions that began to radically change from the late 1970s in Western nations. As Giddens (1991) has noted, the period from the late 1970s to the 1990s was marked by a major transformation in Western states, epitomized by the emergence of neoliberalism as a driving force in right of center politics, particularly in the United States and United Kingdom. The basic philosophy of neoliberalism can be described as

> …scepticism over the capacities of political authorities to govern everything for the best; vigilance over the attempts of political authorities to seek to govern. Its language is familiar and needs little rehearsal. Markets are to replace planning as regulators of economic activity. Those aspects of government that welfare construed as political responsibilities are, as far as possible, to be transformed into commodified forms and regulated according to market principles.
>
> Rose and Miller, 1992: 98

The impact of this type of political philosophy was a wholesale transfer of responsibilities for managing the environment (as well as other assets) to the market place. The state's role would be to provide light touch regulation and at a distance, but in essence, market mechanisms had to drive environmental management and in so doing, the priorities of environmental protection and economic growth were brought into ever sharper focus as neoliberal states considered the most effective ways of maintaining economic competitiveness and tackling environmental problems.

It was the notion of sustainability that enabled politicians to manage this increasingly difficult balancing act. Published in 1987, the United Nations Environment Program's *Our Common Future* (WCED, 1987) institutionalized the term sustainable development, defining it as

> Development that meets the needs of current generations without compromising the ability of future generations to meet their own needs.
>
> WCED, 1987: 8

The era of sustainability was formalized through the United Nations World Summit in Agenda *21* (UNCED, 1992), a prospectus and policy framework for promoting sustainable development. And so was born the current political consensus that now dominates Western discourse on the environment. In this discourse, it is possible to have both economic growth and protect the environment, through carefully balanced relationships between the state, markets, private enterprises, and, most crucially, 'citizen/consumers.'

The notion of the citizen/consumer emerged in the early 2000s as a way of recognizing the ways in which the state simultaneously encourages prescribed forms of citizenship and does so through a framework that places choice at the heart of decision-making. Clarke et al.'s (2007) authoritative study of the citizen/consumer concept emphasizes many of the inherent contradictions that lie at the heart of encouraging citizens to be environmentally responsible, while at the same time promoting such responsibility through a choice model that drives economic growth and ever greater consumption.

This apparent contradiction in the development of sustainable lifestyles policy, as it has been framed in countries like the Untied States and the UK, has been the subject of critical writing from social scientists (Barr et al., 2011), who have argued that this particular framing of environmental responsibility and its operationalization through the consumer growth-orientated model, is a form of libertarian paternalism (Jones et al., 2011). In this way, States promote existing forms of capitalist hegemony through free-market principles and consumer 'choice,' but they also exercise power at a distance through paternalistic notions of 'right' ways of living, for example, by guiding consumers in the ways that they should consume products, use energy, save water, and recycle waste. Indeed, in recent years, the evocation of libertarian paternalism has been formalized through the publication of the highly influential book *Nudge* (Thaler and Sunstein, 2008). This book, published by two academics at the Massachusetts Institute of Technology, highlights the ways in which consumer choice can be maintained while guiding consumers to 'better' choices through alterations in what they term the choice architecture. Accordingly, a nudge can be described as

> … any aspect of the choice architecture that alters people's behavior in a predictable way without forbidding any options or significantly changing their economic incentives. To count as a mere nudge, the intervention must be easy and cheap to avoid. Nudges are not mandates. Putting the fruit at eye level counts as a nudge. Banning junk food does not.
>
> Thaler and Sunstein, 2008: 8

In this model, behavior change and the promotion of sustainable lifestyles is about managing choice within a consumption-based framework. As such, it has much in common with a closely aligned approach is social marketing. Defined by French et al. (2009) as the use of conventional marketing principles to promote a social good, social marketing aims to use positive messages, targeted at specific consumer segments, to promote incremental behavioral change and as Doug McKenzie-Mohr (2000) has noted, it offers practitioners a feasible means of achieving better results in programs designed to promote sustainable forms of behavior, like recycling or energy saving.

In these ways, the political notion of sustainable lifestyles is one that is largely locked down into a particular framing, based on a set of state-led prescriptions about citizenship responsibilities on the one hand, and facilitated by architectures of choice on the other. Pragmatically, sustainable lifestyles are defined by a series of consumer-based decisions. For example, the UK's Department for the Environment, Food and Rural Affairs (DEFRA) published a *Framework for Pro-environmental Behaviors* (2008) in which it advocated the following 12 types of action:

- install insulation products,
- better energy management and usage,
- install domestic microgeneration through renewables,
- increase recycling and segregation,
- waste less (food),
- more responsible water usage,
- buy/use more energy-efficient (low-carbon) vehicles,

- use car less – seek alternatives for short trips (<3 miles),
- reduce nonessential flying (short haul),
- buy energy-efficient products,
- eat food locally in season, and
- adopt a diet with lower environmental impacts.

In essence, these actions mirror what many current attempts to encourage sustainable lifestyles have become – a set of discrete and often quite inflexible prescriptions for behavioral change. As we will see at the end of this article, this approach is being challenged by some scholars, who are arguing for a greater emphasis to be placed on more ambitious and creative ways of understanding sustainable lifestyles, which challenge the existing economic hegemony.

The Psychology of Sustainable Lifestyles

If neoliberalism has framed the notion of sustainable lifestyles as a viable approach for tackling global environmental concerns, then it is the psychological approach to behavior that has characterized the intellectual tradition, which has itself become deeply implicated in the ways in which policy makers understand behavior and seek to change it (Jones et al., 2011). The tradition of psychological approaches to understanding environmental behavior (which is used interchangeably here with sustainable lifestyles) is one that started in the late 1960s with concerns over energy use, later developing to incorporate concerns over recycling and water conservation. There is also a tradition in transport psychology that has explored how we understand travel habits and behaviors (Heath and Gifford, 2002).

Psychological studies of sustainable lifestyles have tended to follow the epistemological tradition of mainstream psychology, which is largely theory-led and utilizes quantitative social science methods to develop understandings of behavior. In this tradition, it is familiar to see generic models of behavior applied to specific issues, like the prediction of participation in environmental programs. For example, models like Fishbein and Ajzen's (1975) Theory of Reasoned Action have been used to explore the role that attitudes, norms, and perceived behavioral control exert on an individual's intention to act and their reported behavior. In these models, measures of particular constructs are developed, tested, and applied to ensure item validity and are operationalized through questionnaire surveys, being analyzed using multivariate statistical techniques like regression analysis, path analysis, and factor analysis (Fishbein and Ajzen, 2009). A useful example of this type of research is Anable's (2005) survey of tourists and their environmental attitudes, and the extent to which they were willing to reduce car driving as a way of reducing their carbon emissions. Using the Theory of Planned Behavior, Anable constructed appropriate measurement items for a questionnaire of National Trust Property visitors in the UK and utilized a factor analysis to explore the ways in which the constructs used in this model were reflected in her own data. In so doing, she was able to identify six segments of the population according to their environmental attitudes toward car driving and to use the Theory of Planned Behavior to suggest the reasons for variation in each segment.

A second strand of research in this area draws on a range of empirical insights from social and environmental psychology to develop a series of frameworks for understanding proenvironmental behavior. Since the early 1970s, psychologists have attempted to correlate a large number of variables to proenvironmental behavior and these have often been focused around the sociodemographic composition of populations. As documented in seminal works, Hines et al. (1987), Schultz et al. (1995), and Bamberg and Möser (2007) have identified, for example, that those with greater levels of environmental consciousness and reported proenvironmental behavior tend to be younger, female, have more formal education, be on higher incomes, and come from a politically liberal constituency. Indeed, meta-analyses of this type of research reveal the tendency for environmentalism to be a largely middle-class activity (although this is based on the explicit link between stated environmental attitudes and corresponding behaviors, and says little about actual environmental impact). As Barr and Gilg (2006) have outlined, a broader reading of the psychological literature on proenvironmental behaviors indicates that the correlation of demographic factors to behaviors relates to a set of situational factors that influence proenvironmental behaviors, such as environmental and behavior-specific knowledge, past experience of engaging in sustainable behaviors, and access to the resources and facilities that promotes or prevents participation. Within the household context, Barr and Gilg (2006) highlight, for example, the role of access to curbside recycling facilities as a major situational factor influencing participation in recycling.

Two other broad categories of influences on proenvironmental behavior can be identified from this psychological tradition. As Barr and Gilg (2006) argue, both social and environmental values and psychological variables are of importance. In the first instance, the seminal work of Stern et al. (1995) has demonstrated the role of social values in relation to proenvironmental behavior, not least the tendency for those with altruistic values and with an openness to change to be more likely to adopt proenvironmental practices (as opposed to those with egoistic and conservative values). Indeed, in describing specific values toward the environment, Dunlap et al.'s (2000) New Ecological Paradigm highlights the ways in which those individuals with ecocentric and biospheric values (e.g., human equality with nature, acceptance of environmental limits) tend to have more proenvironmental attitudes and behaviors.

Alongside the role of values, psychological factors are those variables, which are comprised of individual psychological attributes that have been found to influence an intention to act in a proenvironmental manner. These are many and varied and include the role of social and subjective norms (the influence of others and the acceptance of this by individuals), self-efficacy (the belief in one's ability to act), response efficacy (the belief in one's actions to have the desired effect), perceived threat of the problem at hand, and the perception that the behavior is convenient and easy to undertake. As Schultz et al. (1995) note, the 'list' of factors is seemingly every growing and one challenge for this broad strand of psychological inquiry is to explore how there can be conceptual integrity with such a large number of variables.

Accordingly, psychological approaches to understanding sustainable lifestyles have tended to focus on theory-led or theory-informed empirical studies of quantitatively measured constructs of behavior, attitudes, and other variables. The popularity of this approach has been significant in influencing policy and it is to the second broad strand of research approaches that has sought to apply this approach in a policy setting that this article now turns.

Policy Approaches for Promoting Sustainable Lifestyles

As Jones et al. (2011) point out, in countries like the UK, the psychological approach has been favored above others in its adoption as a pragmatic tool for creating and implementing policy. Often known as behavioral economics because of the dominance of economics as a policy-determining discipline in government, the psychological approach has offered a reassumingly 'scientific' basis for exploring and understanding behavior, underlain as it is by logical positivist assumptions, quantitative methods, and statistical rigor. Indeed, psychological approaches have been translated from theoretical ideas into apparently workable policy tools through the twin approaches outlined earlier in this article (Nudge and social marketing) and have been enthusiastically adopted by government departments and agencies seeking to apply psychological theories for policy making. Although many agencies have been keen to adopt the principles of choice architecture and social marketing (see the UK's National Social Marketing Centre as an example; NSMC, 2013), one of the best examples of how social marketing has been incorporated into government policy making in a country like the UK is DEFRA's (2008) *Framework for Pro-environmental Behaviors*. Published at a time when behavioral change was beginning to make a major impact in the UK central government policy making, this document highlights the influence and role of social marketing as a technique for guiding policy. Within the document, key behavioral goals are outlined (listed earlier in this article) and seven core segments of the UK's population are identified according to their (quantitatively measured) environmental attitudes and reported behaviors. As the document outlines, policy for promoting sustainable lifestyles rests on determining the right marketing mix for promoting specific changes in individual behavior through engagement with particular segments of the population. Critically, these behavioral changes are framed within the context of making 'better' choices, a clear example of Jones et al.'s (2011) argument concerning the role of libertarian paternalism in behavioral change policies.

Accordingly, the translation of psychological insights from quantitative research into policy making and program implementation has been achieved through a high level engagement of politicians and civil servants with the notion of individualized, quantifiable, and theory-led understandings of behavior, to the extent that the UK government currently has a Behavioral Insights Team (2013) at the very center of government, adjacent to the Prime Minister's Office.

Recognizing this particular framing of sustainable lifestyles is important because it illustrates the links between behavioral science and policy making that have come to dominate Western approaches to understanding and promoting sustainable lifestyles. Yet these particular understandings do have their critics and it is to a different version of sustainable lifestyles that this article now turns, initially by outlining the third intellectual approach to behavioral change and then to the broader issue of how we might envision sustainable lifestyles for the future.

Social Practices and Sustainable Lifestyles

In framing sustainable lifestyles as a set of discrete and quantifiable behaviors acted at the individual level, there is a danger that the broader context of such academic and policy initiatives is missed. Sociologist Elizabeth Shove (2010) has strongly argued for social science to adopt a different approach to that adopted by psychologists and the majority of the policy making community by exploring the following three key issues: the role of 'environment' in understanding sustainable lifestyles; the importance of the individual as the scale of reference; and finally the mode of research and analysis as a way of uncovering social practices.

In the first instance, Shove (2010) argues that in focusing the attention of analysis on specific environmental concerns (for example, focusing on changing energy behaviors as a way of tackling carbon emissions) researchers fail to recognize the complexity of 'social practices,' which

> … are conceived as being routine-driven, everyday activities situated in time and space and shared by groups of people as part of their everyday life.
>
> Verbeek and Mommaas, 2008: 634

Accordingly, Shove argues that to understand the environmental implications of behaviors, researchers need to explore the underlying practices that relate to how people live their everyday lives. Using the example of energy behaviors cited above, what is of interest is not a specific behavior that might have an impact on energy use and carbon emissions, but rather the social practices that lead to ways of living that result in high carbon emissions. Such an analysis requires a deep understanding of how social practices have formed over time and what broader social contexts come to frame such practices.

This leads to a second concern, which is a need to move beyond the individual as the frame of reference, to look at how individual behaviors are reflections of wider social practices, which are connected through shared understandings of what constitutes normal or everyday practice. A good example of this might be the fundamental changes we have witnessed in water use in developed nations. Practice researchers would not necessarily start with an isolated analysis of individual water use behaviors nor indeed the environmental attitudes of individuals, but would rather seek to appreciate how it is the case that in recent years the amount of personal water use has increased. The questions that such researchers would ask relate to how water use practices have changed over time, how common norms of water use have altered across populations, and what drivers can be identified for such changes, such as

shifting notions of what it means to be clean and to experience comfort from water-based practices. Inevitably, this takes the scale of analysis away from the individual and toward the social and cultural, emphasizing the role of changing architectures and contexts that surround individuals.

A third and final argument advocated by social practice researchers relates to the ways in which scholars explore these issues. Whereas psychological and policy-orientated approaches place emphasis on quantification and statistical representativeness, social practice researchers focus on the role of context, situation, and do so through the use of qualitative methods. Although there is variation in the types of qualitative methods adopted, popular techniques include participant observation, in-depth interviews, focus groups, and other forms of ethnography. Critically, to understand social practices, many researchers have chosen not to begin with a theoretical framework, but instead to use a grounded theory approach, which starts by accumulating significant amounts of data and information from participants and builds a situated theory from these data.

In this way, a social practices approach acts as a counter (and often critic) to the psychological and dominant policy-making approaches. Advocates often contest the logical positivist assumptions of the psychological perspective, arguing that this encourages policy makers to prefer rationalistic, theory-driven, and linear models of behavior that do not reflect social reality (Owens, 2000).

Social Transformation and Sustainable Lifestyles

Thus far this article has explored the current state of social scientific understandings of so-called sustainable lifestyles and has emphasized both the embedding of this term in contemporary forms of political economy and the ways in which policy makers have adopted particular definitions and methods for understanding and promoting sustainable lifestyles. The sociological influence over debates on such research and the advancement of thinking on social practices has, to a certain extent, provided a counter to this intellectual dominance of psychology. However, to really understand sustainable lifestyles there is a need to explore what this notion might look like if we extracted it from contemporary policy debates on incremental behavioral change, dominated by the 'small change' agenda of recycling habits, energy conservation, and minor changes in travel practices. Rather, can we be more ambitious in our understanding and promotion of living more sustainably?

Crompton and Thøgersen (2009) have highlighted that if all we ever advocate is small change, the outcome will be a proportionally small change for the environment. They argue for a more radical rethink of how our economic system and associated social practices relate to the environment and what changes in society will be needed to radically reduce carbon emissions associated with consumption and, ultimately, to promote ways of living that enable humans to live with less, not more. This is an argument, which has been pursued by a number of social scientists, most passionately by Shove (2010) and Dobson (2010). Although they focus on different components, their approach is to argue that the high carbon lifestyles that most people in the Western world lead are the direct result of a largely unquestioned and seemingly unchangeable set of economic assumptions, grounded in the argument that economic growth is the only way to develop and prosper. It is not until these basic assumptions are unpacked and changed that shifts in social practices will be achievable that will offer the prospect of tackling global climate change. In this sense, the argument becomes one not about the specific of sustainable lifestyles, but rather one about economic assumptions, contemporary living arrangements, and the very basis of what most people in the West consider it means to live a 'good life.'

In challenging researchers and policy makers to reconsider sustainable lifestyles in this radicalized context, advocates of social transformation argue that such changes are not instrumental but necessary for encouraging greater social equity and for dealing with an emergent, albeit often dismissed, second global emergency, that of resource scarcity. Epitomizing what it might come to mean to live a 'sustainable lifestyle,' authors like Kunstler (2005) argue that with the onset of oil price rises, a peak in economically viable oil production and shortages of other energy sources, individuals and communities will have to reengage with lost practices of sustainable living that reconnect us with nature and different forms of place-based community.

Although more radical changes in sustainable lifestyles as advocated by these authors are certainly off the policy agenda at present, they merit attention because they have been fundamental in framing local and growing community responses to environmental change and resource scarcity in many nations. As Hopkins (2008) points out, a transition to a low-carbon, low-oil-dependent society will require major social and economic change and this has been reflected in the growth of the Transition Movement (Transition Network, 2013), which advocates place-based, local strategies for living sustainably and for thinking about what a quality of life without abundant cheap energy might look like. This is likely to involve major changes in all parts of our lives, from our personal mobility (working and socializing close to home) to our shopping practices (buying local, seasonal produce) and to changes in how we view 'work' (with manual occupations like food growing and mechanical trades becoming more important once again). In sum, this important and emerging strand of sustainable lifestyles research argues that our approach to behavioral change will need to be much more radical to deal with the challenges of a climate-changed and resource scarce world.

Conclusions

Sustainable lifestyles is a deceptive term; it appears to be something we might all be able to describe, but in fact it is one that is politically implicated, intellectually complex, and definitionally problematic. Indeed, it is a term that is likely to mean something quite different in a decade's time. From an academic perspective, the intellectual schism between psychological and sociological approaches is problematic and is likely to endure for as long as one approach is favored over another from a policy perspective. Indeed, because of the dominance in policy making of quantifiable, 'scientific' approaches, there is a sense that the notion of sustainable lifestyles has effectively become politicized and narrowly defined as a relatively

unambitious set of behaviors that reflect the political priorities of the day.

Rather, this article has tried to demonstrate that we need to think about sustainable lifestyles as a problematic term, poorly defined and politically loaded. If we can accept this, then we must also move on intellectually to more fertile ground. We must consider what a sustainable lifestyle might look like in times of scarce resources and a world changed by anthropogenic global warming. This requires a much more ambitious social science, one that challenges economic hegemony in the name of promoting social and environmental justice and a role for citizens that is democratic and driven by the principles of participation and localized decision-making. Placed in this context, the achievement of sustainable lifestyles is a long way off.

Sustainable Practices

Abstract

This article gives an overview of the 'practical turn' in the social sciences and its reception within sustainable development research and debates more generally, and studies of (un)sustainable consumption in particular. It offers a critical review of opportunities and limits of practice research on sustainability issues and outlines potential further developments in this field.

Introduction

Practice theories are at the cutting edge of sustainable consumption research and related policies. They claim to offer an alternative route to conceptualizing the dynamics of social change by addressing both the continuity and innovativeness of human behavior. Much practice-theoretical research focuses on daily routines, that is, the everyday doings of people that are carried out with the aid of objects, such as tools, instruments, or the surrounding infrastructure. Since practices involve both physical and verbal activities, they need to be investigated using a mix of research methods, including interviews, observations, document analysis, and statistical data. Practice theories draw attention to core issues that frequently remain unaddressed by behavioral approaches, such as the role of large-scale infrastructure or material objects as participants in everyday life. When it comes to behavioral change toward a more sustainable way of living, practice theories pose the critical question whether it is actually possible to steer or govern social practices and, if so, how this can be done.

This article seeks to outline the main characteristics of practice theories before linking them to sustainability issues. The main focus will be on current sustainable consumption research. The third section discusses methodological issues surrounding empirical research on sustainable practices, while the concluding part outlines the main aspects of research required to foster sustainability in various fields of society.

The 'Practice Turn' and Its Consequences

The 'practice turn' was proclaimed some years ago and has since triggered considerable debate in the social sciences on how to conceptualize human behavior and the social (Schatzki et al., 2001). Despite the heterogeneity within the field of practice theory, the unifying assumption is that societal phenomena (e.g., individual behavior, collective activities, or sustainability processes) can be explained neither by methodological individualism (e.g., rational choice theory, sociological action theories) nor by structuralist or normativist approaches (Reckwitz, 2002). Instead, practices are treated as the core units of investigation and analysis. Despite the multitude of potential definitions, the view of a practice as a stable, yet adaptable nexus of doings and sayings that exists independently of the individuals who engage in it has largely established itself in the debate. More far-reaching conceptualizations view practices either as agents between individual activities and social structural moments (Giddens, 1979) or substitutes for social structures.

From an analytical perspective, it makes sense to view a practice as an organized entity on the one hand, and as the performance of such an entity on the other (Schatzki, 2002). While the former concentrates on the different aspects that constitute the organization of a practice, the latter looks at the activities carried out by the actors involved. Organizational aspects include understandings, rules, and teleoaffective structures or *leitmotifs* that constitute a practice. Understandings refer to those physical and mental skills that individuals require to engage in a practice. Rules include instructions for actions that are used either consciously or subconsciously by the actors involved. They can be implicit or explicit and range from virtually uncodifiable (e.g., rules of thumb, hints) to strongly codified (e.g., regulations, laws). A teleoaffective structure incorporates all target-oriented and affective orientations that determine which activities are suitable and appropriate enactments for a practice and which are not. The sociomaterial context in which a practice is carried out is sometimes viewed as a further organizational aspect (Shove et al., 2012). In contrast, the understanding of a practice as the performance of an activity assumes that the practices of the actors must be enacted through appropriate doings and sayings to have an effect in their societal context. Accordingly, the focus is directed toward various discursive and nondiscursive, physical, and linguistic activities which human (and in some approaches also nonhuman (Mol, 2002)) actors carry out when they engage in a practice. At the same time, there is a strong focus on the material embeddedness of these activities, for example, how a sequence of motions is carried out within a particular sociomaterial space, what artifacts and behavioral scripts are needed to do so as well as the level of involvement of other beings (Schatzki, 2010).

The sociomaterial context of practices is often (not always) understood as networks of human and nonhuman beings, organisms, and artifacts, which together with the performance of corresponding practices constitute the social site in which an individual is located. Here, individuals are viewed as carriers of social practices, a perspective that contrasts with both the consciousness philosophy foundations of (neo-)Marxist practice theories and more recent Foucaultdian subjectivity-oriented approaches. Consequentially, individual subjectivity or the adoption of a particular lifestyle is not attributed to individual performance. Instead, the focus is on how practices

and their sociomaterial contexts facilitate, encourage, shape, or prevent the formation of subjectivity or the adoption of a particular lifestyle.

There is great diversity in the field of practice theory and research. Different social science disciplines have adopted different practice-theoretical approaches. Moreover, a large number of empirical studies exists on different practices like driving (Thrift, 2004), dancing tango (Littig, 2013), enacting urban imaginaries (Jonas, 2014a), or eating (Shove and Spurling, 2013). These studies often highlight the need to combine practice-theoretical concepts with elements drawn from other areas of social scientific inquiry (such as the sociology of consumption, time-space geography, or gender studies) to produce fertile insights. On the other hand, these existing studies also reveal that individuals are involved in the performance of many different practices, which may or may not complement, overlap, or exclude each other.

As a result, the focus of both theoretical debates and empirical research is now moving toward bundles of practices, the extent to which the practices in these bundles are linked to each other, how they emerge, reproduce, and change as well as their connections with other bundles of practices and associated sociomaterial orders. As far as the types of links between them are concerned, experts differentiate between randomly ordered ensembles, networks, closely linked webs and stable complexes (Jonas, 2014b), or bundles and complexes (Shove et al. 2012). These in turn are positioned either on one level, thereby suggesting a 'flat ontology' (Marston et al., 2005), or on several societal levels (micro–meso–macro) that characterize more traditional multilevel approaches. There are also conceptual alternatives with regard to how practices are created, reproduced, and transformed. These draw on evolutionary theory, innovation theory, or cooperation and conflict sociology and address issues of overlap, competition, or relationships of dominance between practices. Practice theory approaches thus treat societal phenomena in a new way by focusing on the 'space' between individuals' activities and wider social structures, which is often ignored in more individualist or structuralist approaches.

Sustainability and Praxeological Research

The term 'sustainability' is one of those normative concepts that defies clear-cut definition. Prevailing approaches describe sustainability using a so-called three pillar model which assumes that economic development, environmental protection, and social justice and equity can be reconciled and should be given equal priority. In practice, however, economic and environmental interests are frequently placed over and above the social pillar (Littig and Grießler, 2005). The field of interdisciplinary sustainability research is highly diverse (Fahy and Rau, 2013); however, most sustainability policies have all taken advantage of the relative fuzzyness of the term sustainability and primarily propagated and promoted technological advancements ('green' technologies). Moreover, measures to change individual attitudes, behaviors, and habits have been given priority over other forms of intervention. A strong focus on responsible consumerism and corresponding choices demonstrates this. These approaches to (un)sustainable consumption build on authoritative behavior theory, adopting the simple formula that (frequently moralizing) education and instruction will change people's attitudes, which in turn transform their behavior and choices (e.g., OECD, 2013). This 'ABC logic' has recently been criticized, particularly from a practice theory perspective (Shove, 2010). Others suggest that dominant approaches to sustainability research and policy that endorse ABC thinking and that adopt phrases such as 'green economy' or 'win–win situation for the market, the state and the environment' are acquiescent to prevailing neoliberalization processes (Banerjee, 2003), neglect aspects of social inequality and justice and promote a feminization of environmental protection by shifting responsibility for sustainability efforts to private households (Littig, 2001). In this context, practice theory approaches have been recognized as a credible alternative.

As a consequence, mainstream sustainability policy is neither able to grasp the societal relationship with nature (Becker and Jahn, 1998) nor can it offer effective sustainability solutions. In practice, many sustainability strategies continue to pursue ecological modernization, above all through a greening of the economy. From a global perspective, such modernization projects are frequently exclusive and selective (Brand, 2010). Given the rapid growth in the world population, the increasing consumption of resources from the emergence of a global middle class (Brand and Wissen, 2012), the consequences of climate change (IPCC, 2007), and the unprecedented surge in both urbanization and slumification (Davis, 2006), sustainability cannot be separated from questions of social justice. In fact, as far as the industrialized nations are concerned, they require a radical change in production and consumption processes that goes far beyond the promotion of green technology advancement and individual changes in behavior and that bring about a transition between different sociometabolic regimes (*see* Social Ecology).

Empirical research based on practice-theoretical approaches has been conducted for diverse areas of consumption and different aspects of society. These studies not only illustrate the limitations of stand-alone technological solutions to sustainability problems, they also suggest that individual choices or changes in behavior are only of marginal relevance. Even though they cover a broad spectrum that extends from the exploration and transformation of nonsustainable work practices (Hargreaves, 2011), the adaption of sustainable agricultural practices and relevant research in the fields of mobility, energy use in private households, or leisure through to nutrition, most of the studies conducted to date can be assigned to the field of sustainable consumption (e.g., Shove and Spurling, 2013). The prevailing concept in sustainable consumption (*see* Sustainable Production and Consumption) is based (above all in the global north) on the notion that private consumer behavior, i.e., the purchase and consumption of market goods and services, has a significant influence on global economic, social, and environmental development. A goal of sustainable consumption is thus the development and distribution of (technologically) efficient and sufficient collective consumption patterns, requiring fundamental changes in both individuals' behavior and prevailing structures or 'systems of provision' to ultimately reduce the use of resources and energy.

From a praxeological perspective, and given the criticism directed at this prevailing understanding of sustainable consumption (Dolan, 2002), the term contains a broad range of practices in which individual actors participate to perceive, acquire, use, exploit, and dispose of not only market-brokered but also nonmarket-brokered entities without damaging themselves, their environment, or the need to satisfy future generations (Jonas, forthcoming). It becomes clear that, strictly speaking, there is no such thing as a sustainable consumption practice per se; instead, consumption is seen as a key component of many very different bundles of practices that trigger distinction effects in the social space. This notion assumes that sustainability must always be measured in relation to other aspects (e.g., power), and any assessment of the effects of the corresponding practices must give due consideration to related contexts. The activities of the individuals involved have more in common with the image of a practitioner than that of a consumer. Here, connections to lifestyle and milieu concepts prove fruitful because they emphasize the involvement of collectives of actors in practice bundles. However, corresponding studies carried out, for example, in Europe (Barr et al., 2011) suggest there is no such thing as a consistently sustainable lifestyle (i.e., sustainable way of living). Instead, nonsustainable aspects (e.g., climate-damaging flights) coexist alongside sustainable aspects (e.g., eco-vacations in faraway destinations) in the lifestyles studied and can be seen as the result of lifestyle-segment-specific practice bundles (in this case, mobility and vacation) (*see* Sustainable Lifestyles). Collectively accepted, environmentally aware rhetorics of action and the individual balancing of environmentally friendly and harmful behavior help to reduce cognitive dissonances and legitimize individual wrongdoings (Littig, 2001). If such practice bundles from different lifestyle segments are closely and complexly linked to each other, the chance of developing a consistently sustainable lifestyle becomes very slim.

Other studies offer more detailed insights into the sustainability, performance, and organization of very different practices, particularly in the above-mentioned fields of mobility (Middleton, 2011), energy use (Spinney et al., 2012), and other areas of everyday life (Gregson et al., 2009). These studies show that the performance of everyday practices, like driving or walking, eating, showering, or using a laptop, is primarily shaped by habits, routines, and day-to-day rules. Rational deliberations and 'freedom of choice' that are so popular in mainstream sustainability policies are the exception rather than the rule. They also underline the key role of different perceptory senses in carrying out practices. Moreover, affects and emotions lead people to engage in some practices and exclude others. In addition to corresponding practice-specific competences and tacit and explicit rules, teleoaffective *leitmotifs* also reproduce dominant practices, e.g., images of motorized personal transport that have established themselves in many societies in relation to driving. At the same time, they suppress the development and spread of alternative, so-called low-CO_2 practices like walking and cycling (or using public transport). More importantly, dominant practices such as car-based mobility are facilitated by corresponding sociomaterial infrastructures, the planning and implementation of which took only insufficient (if any) account of alternative, more sustainable practices such as walking and cycling, and which can often only be changed with considerable effort and at great cost.

Interestingly, everyday habits that are core elements of (un) sustainable practices prove to be far more flexible than is often assumed. Furthermore, they serve as core anchor points that supply the necessary rhythms and predictabilities of everyday life. In this connection, practices and the customs they involve are always tied to sociospatial settings. In the United States, but also in many European countries, the above-mentioned practices of walking or cycling, which are far more energy efficient than driving a car, have been "marginalized by autocentric planning, engineering, politics, and legal regimes that manifest as laws and infrastructure incompatible with active modes" (Nixon, 2012: 1664). Accordingly, initiatives to promote environmentally friendly mobility will remain of little success until such regimes are adapted to the needs of walking or cycling practices. At the same time, these studies point out that there is no one single practice of walking. Instead, walking practices vary from strolling and sauntering through to purposeful hikes. While they share a whole number of commonalities, they also have their differences. Moreover, we also have to determine the relevance of gender or milieu-specific, age-related, or other nonagent-related aspects (e.g., the weather) for such practices and ascertain whether the performing of such practices in the available or planned sociomaterial spaces are linked with positive sensory perception opportunities. Hence, infrastructural changes to facilitate more sustainable practices also need to be taken into consideration when trying to change behavior (Dangschat and Segert, 2011).

The relevance of habits for the course of societal processes currently receives renewed attention not only in practice theory based sustainability debates but also in related areas of sustainability research and practice (Warde and Southerton, 2012; Strengers and Maller, forthcoming). From a praxeological perspective, it makes sense to differentiate between habits and practices. All habits can be designated as practices, but practices are often more than just a set of habits. Many of the empirical studies mentioned above demonstrate the flexibility of practices for a context in which habits are grasped not as primarily rigid patterns of behavior but as partially flexible and creative processes that facilitate adaptation to different situations. Habits and routines are thus not opposites to reflexive action but form the necessary conditions for it. This discussion can provide important impetus for the formulation and development of promising sustainability policies because it shifts the emphasis away from trying to suppress unsustainable habits (e.g., traveling extensively by car and/or plane, maintaining an energy-intensive lifestyle) by raising awareness and increasing reflexivity. Instead, attention is drawn toward how established habits can be replaced by sustainable alternatives and for which changes need to be made in the sociomaterial context to ensure that more sustainable (bundles of) practices appeal more to their potential agents than currently established ones.

Methodology and Methods

Practice theory is not only a specific strand of social theory. As demonstrated above, many examples exist of empirical

research into sustainable practices. Interestingly, a practice theory perspective also requires a specific methodological approach which takes a 'practical turn' toward research objects, i.e., the phenomena studied using scientific practices. Praxeological analyses situate their research objects in fields of embodied, materially mediated activities and processes which are organized along collectively shared forms of practical knowledge and competences. The praxeological perspective is a particular lens on social phenomena which emphasizes the collective organization and mutual interdependence of social life. In their investigation of practices, practice theory based approaches often seek to examine the very research practices that underpin these investigations. In other words, they include 'doing science/research' aspects, i.e., the research practices in relation to the research object. This immediately raises interesting methodological questions.

Firstly, there is considerable disagreement among advocates of practice theory regarding the methods that are suitable for studying social practices. Participant observation was long held to be the primary research method. Meanwhile, other methods such as discourse analysis, qualitative interviews, and extended ethnographic research increasingly form part of the methodological repertoire. John Law, Annemarie Mol, and Marianne de Laet all use the term 'praxiography' to refer to a special research approach which stresses the need to allow the actual field to define the methods used. With analogies to Actor-Network-Theory, they view practice as 'enactment' in the sense of an interaction of human and nonhuman participants. In their empirical studies to date, they even select objects as the starting points of their research, such as the 'Zimbabwe Bush Pump' (de Lait and Mol, 2000) or the 'Cumbrian Sheep' (Law and Mol, 2008). Despite the dominance of qualitative modes of inquiry, some argue that a practice theory perspective does by no means preclude quantitative research. Nonetheless, there are currently only a few examples which demonstrate the extent to which quantitative methods can be used beyond the numeric-descriptive recording of practices (Cheng et al., 2007).

Outlook

Practice theories can be seen as an alternative approach to activity or behavioral theory approaches. Despite their breadth and heterogeneity, practice theory approaches are unified by their fundamental criticism of individualistic notions of sociality on the one hand, and structural determinism on the other. This said, sophisticated practice theory debates in the social sciences are often contrasted with a comparatively limited use of their concepts in empirical research. These empirical studies are also scattered across relatively distinct research fields that rarely interact (e.g., interpretive policy analysis, practices in and of organization, sustainability, etc.). To assess the merits of practice theory for empirical research, greater interlinkages between these disparate research fields would be expedient. Recent multidisciplinary international conferences (The Institute for Advanced Studies in Vienna hosted an international conference on practice theories and research in June 2013. Publications are planned and will be forthcoming in 2014. See: http://www.ihs.ac.at/conferences/practices/(accessed 25.09.13.).) and workshops are first steps toward achieving this (Warde and Southerton, 2012). Moreover, research into (un)sustainable practices would also profit from comparative perspective.

One key criticism directed toward social practice theorists is their apparent inability or unwillingness to suggest strategies and policies that seek to intervene in the trajectories of practices to address 'real-world' policy problems. Few published studies exist that seek to apply social practice theories in the territory of changing practices, i.e., to identify opportunities to disrupt, reorient, or redirect social practices in more sustainable directions (e.g., Shove and Spurling, 2013; Davies et al., 2014). There is clearly still a lack of research into particular questions like how to design effective political interventions against a backdrop of practice theory considerations. Last but not least, the question remains whether and to what extent the (political) steering of practices is possible given the complex linkages between different practices. Thus, more empirical praxeological experiments are needed in the future.

Abstract

Sustainable production and consumption (SPC) is both a policy area and a multi- and interdisciplinary research agenda that seeks to address the transformation of society toward environmental and social sustainability. The SPC field encompasses diverse research topics and theoretical approaches, often characterized as falling into stronger and weaker versions, defined by commitment to more or less systemic socioeconomic change. Fault lines within the field reflect fundamental controversies within the social and behavioral sciences more broadly, such as the structure–agency antinomy. Major theoretical developments within SPC include novel conceptual frameworks for production–consumption systems and reconceptualizations of consumption.

Introduction

Sustainable production and consumption (SPC) is best understood as both a policy area and a multi- and interdisciplinary research agenda rather than a fully coherent social and behavioral scientific field. The field is also referred to as 'Sustainable Consumption and Production' (SCP), usually with a concomitant research emphasis, or simply 'sustainable consumption' (often, however, without signaling an exclusion of interest in production). The generic area is referred to as SPC throughout this article without any intended emphasis on a particular research agenda or viewpoint. Research in SPC is conducted by scholars in, primarily, economics, geography, sociology, social anthropology, and social psychology, as well as, inter alia, development studies, marketing, management studies, planning, political science, and public policy. SPC research is also to be found in the interdisciplinary areas of consumer behavior, innovation studies, and organizational studies. Research in the field often seeks to transcend narrowly disciplinary perspectives and this is reflected in inter- and multidisciplinary research programs and publications (e.g., Cohen et al., 2013; Shove and Spurling, 2013; Southerton and Ulph, 2014; Reisch and Thøgersen, 2014).

Definitions of SPC are highly contested, particularly around the manner in which SPC addresses: systemic change on a global level, the demarcation between production and consumption, and between consumption and other social activities. The scope of SPC research is therefore more useful to introduce the field. Useful distinctions can be made between research on the material aspects of SPC (commonly addressed as 'life cycle assessment' (LCA), 'material flow,' or 'environmentally extended input–output analysis' – *see* Industrial Ecology and Life Cycle Assessment), economic aspects (studied at both micro and macro levels), and psychological, social, and cultural aspects.

Technically and instrumentally oriented SPC research commonly addresses improving the environmental performance of production processes and supply chains; product, service, and system innovation for sustainability; and mechanisms for, and barriers to, making consumption more sustainable (including consumer behavior, lifestyles, and symbolic aspects of consumption). Research further addresses corollary policy areas concerning technological innovation and the management of sociotechnical transitions toward sustainability and consumer-oriented policy, as well as related areas of corporate social responsibility, such as stakeholder engagement. Conceptually oriented work in SPC theorizes relations between production and consumption, and systemic change of sociotechnical and socioeconomic systems (e.g., Tukker et al., 2008; Lebel et al., 2008).

A broad range of additional topics are found under the rubric of sustainable consumption, including critiques of consumerism and critiques of SPC policy. Conceptual work in the area theorizes consumption and its relation to wider social activity, as well as the roles and capacities of consumers, social movements, and other collective actors in promoting sustainability. Such theoretical work is commonly in dialogue with empirical studies, and vice versa. Empirical studies address, on the one hand, environmental and consumption-oriented politics, including ethical and political consumption, and the cultural dimensions of sustainable consumption, and on the other, more broadly, the dynamics of everyday practices, the evolution of sociotechnical systems, and the relation of both to transitions toward sustainability (e.g., Cohen and Murphy, 2001; Cohen et al., 2013; Jackson, 2006; Reisch and Thøgersen, 2014; Southerton et al., 2004).

Sustainable consumption is often explored through the broad domains of consumption most critical for environmental impact. There is widespread agreement that transport (or mobility), food, water, housing, and energy-using products account for 70–80% of consumption-related environmental impacts in industrialized nations when measured over the life cycle (Tukker et al., 2010: p. 17). Life cycle here refers to the production of goods and services, their consumption, and their disposal, drawing our attention to the systemic relations between production and consumption. SPC scholars thus conceptualize domains as production–consumption systems and analyze the complexities of changing such systems.

SPC has sought to develop a comprehensive view of the environmental impacts of the economy as a system and to analyze the impacts, dynamics, and potential for change of component production–consumption subsystems. This represents a shift in environmental policy and analysis from the supply-side perspective: the sole focus on producer

responsibility for environmental impacts and the modification of productive processes alone as the mechanism for achieving Sustainable Development (*see* Sustainable Development: An Economic Perspective). Consumption and demand-side management has come to be viewed as a legitimate area for environmental policy making and for social scientific research into the environmental impacts of the economy. Indeed, much of the normative controversy surrounding SPC concerns where on the continuum between production and consumption responsibility for environmental impact lies.

Approaches to SPC, and sustainable consumption especially, are often considered as falling into strong and weak programs, where the weak program reflects incremental reforms to the status quo, and the strong program radical systemic change to the economy and society (e.g., Fuchs and Lorek, 2005; Hobson, 2013). Public and corporate policy approaches, dominated by a focus on technological innovation on the production side and understandings drawn from neoclassical and behavioral economics and social psychology on the consumption side, commonly reflect the weaker program, while the stronger program is usually advocated by critical social scientists and social movements. Proponents of the strong form of SPC reflect quite divergent theoretical and political commitments and often (not always) draw on strong normative critiques of consumption. Important schools of thought include Eco-Marxism (see the journal *Capitalism Nature Socialism*) and Degrowth (*see* Degrowth), although it should be noted discourses of sustainability per se are inherently normative, given their orientation to socioeconomic change.

A common fault line between the weak and strong versions is whether sustainability can be achieved within the conventional economic growth paradigm, or whether 'degrowth,' or absolute demand reduction, is required. Those supporting the former view contend that a decoupling of economic growth from increasing environmental impact is technically feasible, while those supporting the latter view point out that while instances of relative decoupling can be observed, there is no evidence of absolute decoupling on a global level (see Harris, 2013). Associated with this division is an emphasis on the ecoefficiency of production and consumption on the one hand, and on the other, on radical changes in the patterns and levels of consumption. The weak program is criticized as approaching consumption as simply an addition to the older productivist agenda of cleaner production, regarding consumption primarily in terms of problems and opportunities in the demand for more environmentally friendly products. The position toward 'consumer sovereignty' – or the framing of individuals as autonomous consumers who express their preferences through market relations and purchasing decisions – is thus another commonly invoked fault line between the weak and strong programs. The weak program typically endorses a view of sustainable consumption as the aggregate effects of individual consumers' environmental preferences, while the strong program typically endorses a more expansive notion of 'environmental citizenship' and normative criticism of consumer society (Hobson, 2002). While critics of the weak program accuse it of collusion with the neoliberal economic order culpable for the ecological crisis, critics of the strong program accuse it of political infeasibility, or of hijacking sustainability to promote existing political commitments.

The following section will examine the origins and development of SPC as a policy area; SPC as an area of research is intimately linked with the development of international policy initiatives. The final section will examine the variety of SPC research and some key developments within the field.

The Development of SPC Policy and Research

The origins of the field lie in the growth of environmental social science (*see* Environmental Sociology) in the 1970s, following the 1972 publication of the Club of Rome report 'The Limits to Growth' and the United Nations (UN) Stockholm Conference on the Human Environment. However, SPC did not develop as a recognizable field of research until the 1990s when its emergence coincided with the strengthening of international SPC policy. Proponents of the SPC policy agenda have consistently recognized the importance of, and funded, social science research. As well as instrumental insights and analysis, social scientists have offered an ongoing critique of how the epistemological and ideological foundations of policy frames the SPC agenda and associated public discourse (e.g., Cohen, 2001; Hobson, 2002, 2013; Fuchs and Lorek, 2005).

The 'Brundtland Report' of the World Commission on Environment and Development (WCED, 1987) made an important shift in environmental policy discourse, recognizing that sustainable development (*see* Sustainable Development: An Economic Perspective)

> requires the promotion of values that encourage consumption standards that are within the bounds of the ecologically possible and to which all can reasonably aspire…Major changes in policies will be needed to cope with the industrial world's current high levels of consumption.
>
> WCED, 1987: p. 57

The WCED laid the foundations for the 1992 UN Conference on Environment and Development, or 'Rio Earth Summit,' which was the watershed for international sustainability policy. Agenda 21, the summit's voluntary action plan for the implementation of sustainable development called for, in addition to established areas of environmental policy such as pollution control and conservation, "a better understanding of the role of consumption and how to bring about more sustainable consumption patterns" (UNCSD, 1992: p. 4.23), as well as provisions to address global economic and political inequities. The previous focus of global environmental policy on developing world population growth was displaced by 'sustainable livelihoods' for the global South and 'sustainable production and consumption' for the North (UNCSD, 1992).

Another important shift came in the early 1990s with the European Commission's promotion of the 'ecological modernization' of production (see Mol et al., 2009). Ecological modernization proposed a new relationship between production, policy, and environment. The former approach of

'command and control' environmental legislation shifted to one in which economic competitiveness and growth on the one hand and environmental protection on the other were seen as mutually reinforcing rather than antagonistic. Demanding environmental standards were seen as opportunities for, and stimulators of, innovation. The minimization of waste, the increase in resource efficiency, and the maximization of output were seen to go hand in hand.

Over the course of the 1990s the conventional attribution of environmental responsibility for sustainability to producers was increasingly supplemented by a focus on the role of consumers. Consumption became an organizing theme for environmental policy making, especially in Europe, where sustainable consumption was seen as the 'downstream' complement to the ecological modernization of production. This was initially conceived primarily in terms of consumers' influence through demand for more environmentally friendly products. Early definitions of sustainable consumption, such as the 1995 formulation of the UN Commission on Sustainable Development focused on the use of goods and services that improved quality of life while minimizing environmental impacts, over their life cycle, within boundaries that did not compromise the needs of future generations (Luskin, 2007). The concept of product life cycle – from production through consumption to 'end-of-life' management – was important in foregrounding production–consumption systems as integrated wholes.

The focus on sustainable consumption was expanded in the late 1990s through initiatives such as the United Nations Environment Programme (UNEP)'s Sustainable Consumption program and the Organisation for Economic Co-operation and Development (OECD)'s Sustainable Consumption and Production program. The latter supplemented the conventional focus on sustainable products and eco-labeling by seeking to understand "both the driving forces behind specific consumption patterns, and the implications of using different policy instruments to try to change them" as well as "innovative approaches to modifying consumer behavior" (Cohen, 2001: p. 31).

A step change in activity occurred following the 2002 World Summit on Sustainable Development in Johannesburg, which initiated a 10-Year Framework of Programmes on SCP (the 'Marrakech Process'), including activities around 'life cycle thinking,' public policy tools and approaches, advertising and communications, sustainable products and services, and education and training (see Clark, 2007). Numerous national and international policy-related SPC research initiatives were launched in the aftermath of the 2002 Johannesburg summit. The 'Rio + 20' UN Summit in 2012 has adopted a further 10-year SCP framework program that reiterates the tenets of sustainable development laid down in 1992. It calls for the scaling up of SCP and resource efficiency initiatives to contribute to the decoupling of environmental impacts from economic growth while increasing social development (Hobson, 2013). Rio + 20 also saw the launch of a Global Research Forum on Sustainable Production and Consumption, which frames the research agenda in terms of "how to understand the present lock-in in unsustainable consumerist lifestyles and production patterns, and to understand how a possible transition to more sustainable production and consumption patterns and lifestyles could be accomplished" (Vergragt et al., 2014: p. 2).

Sustainable Consumption

The emphasis on consumption must also be seen in the context of the growth of post-Fordist consumer society from the 1970s onward and a concomitant cultural emphasis on consumption activities. While in developed nations CO_2 emissions from the industrial sector fell in absolute terms and there has been success in reducing pollution and waste from production, overall CO_2 emissions, energy use, and material throughput have continued to grow. Moreover, a growing proportion of these environmental impacts can be directly or indirectly related to private households (Michaelis, 2003). The rapid emergence of a global consumer class, particularly in the Asia–Pacific region, has further focused attention on the sustainable consumption agenda.

The area of sustainable consumption attained a certain degree of autonomy from the wider SPC field following 2002, marking a divergence apparent today. The view that consumption should be viewed purely as an economic activity that can be modified through top-down approaches (primarily information provision, such as ecolabeling, and market signals), and the adequacy of using consumers as the agents of upstream change to the productive sphere, began to be challenged by policy makers (Cohen, 2001: p. 34). The UNEP, for example, identified clarifying the meaning of consumption and a more appropriate conceptual schema for production–consumption as strategic areas requiring research (Fuchs and Lorek, 2005: p. 269). The OECD broadened the definition of consumption beyond market choices to use, disposal, and noncommodified goods and services (Southerton et al., 2004: p. 3). This said, mainstream policy initiatives such as the European Union Sustainable Consumption and Production Action Plan launched in 2008 often continue to be framed in terms of improving the environmental performance of products and production technologies and increasing the demand for more sustainable goods.

While the focus on developed world consumption as the central cause of the ecological crisis was welcomed by many scholars, critical social science has been skeptical of the shifting of responsibility onto consumers, of the adequacy of the characterization of human behavior that has tended to go with it, and of the ameliorative mechanisms thus proposed. This framing of the consumption issue has been consistently critiqued as serving neoliberal ideological interests and obscuring the complex relations to production and macroeconomic issues (Fuchs and Lorek, 2005; Hobson, 2002; Southerton et al., 2004). Furthermore, the divergence of sustainable consumption from the earlier sustainable development agenda has tended to see a focus on environmental impacts to the exclusion of social aspects of sustainability, such as issues of equity.

However, a strong case can be made for the focus on consumption through the importance of behavioral or systemic offsets to potential emissions savings through energy efficiency gains, known as rebound effects. Changes in patterns of consumption can offset the environmental gains achieved

through sustainability improvements in productive processes. Improved refrigeration technology, for example, may simply lead to the use of increased refrigerated space at the same cost. Or on a household level financial savings through energy efficiency may simply be recycled into goods and services with their own life-cycle impacts. Efficiencies also spur innovations in products and services that themselves increase demand. Exponential increases in efficiency in computing power, for example, have driven the development of new products and the creation of whole new markets. On the macro level this leads to the argument that increases in energy efficiency actually cause increases in aggregate energy use (Jevons Paradox, see Sorrell, 2009).

Furthermore, increased efficiency may inadvertently naturalize less sustainable needs, conventions, norms, and expectations; such as the need for Internet access to participate in modern life, or conventions of adequate room temperature (see Shove, 2003). Understanding the dynamics of changing social conventions and expectations can lead to deeper understanding of the dynamics of escalating demand and suggest possible modes of intervention.

Moreover, the case for a focus on consumption lies in the need for rapid emissions reduction to ameliorate catastrophic climate change. Short-term demand opportunities for reduction in CO_2 emissions dwarf the short-term opportunities afforded from the supply side. This is principally due to the long lead times in replacing energy infrastructure compared to the life span of consumer goods and vehicles, as well as inefficiencies in electricity supply systems favoring end-use energy reductions over supply-side savings. As the timescale for effective emission reductions has narrowed, it is widely held that timely action is impossible without radical changes to consumption patterns, however radical the changes made in the productive sphere.

Varieties of SPC Research and Key Theoretical Developments

As noted, SPC policy has been dominated by models of human behavior drawn from economics and social psychology. Both share ontological commitments to methodological individualism and a fortiori the assumption that consumption is driven by individuals' choices, which in turn reflect relatively stable preferences, attitudes, or values. Theoretical developments in the field, especially from within sociology (e.g., Southerton et al., 2004) and social anthropology (e.g., Wilk, 2002), have offered a fundamental critique of this position, emphasizing instead social and cultural processes, and the coevolution of social practices on the one hand, and technologies and infrastructures on the other. That said, there have also been important developments within psychology and economics addressing SPC.

Social psychology, and a specific branch of environmental psychology, as well as lesserly sociology, has addressed attitudes toward the environment and 'proenvironmental behavior' (*see* Environmental Cognition, Perception, and Attitudes), the 'spillover' of environmental behavior from one domain to another, and the 'value–action' or 'attitude–behavior' gap, which describes the discrepancy between reported proenvironmental values and obdurately unsustainable behavior (see Kollmus and Agyeman, 2002).

Economic psychology and behavioral economics address sociopsychological aspects of economic phenomena and processes, and have contributed significantly to sustainable consumption behavioral change policies (see Carlsson and Johansson-Stenman, 2012). Emphasizing the role of unconscious and contextual factors in individuals' behavior, this body of work questions the conventional economic notion of rational preferences, and offers insights into a range of irrational consumption behaviors (e.g., the sunk cost fallacy). Economists concerned with sustainable consumption have also provided insights into traditionally sociological areas such as the role of acquired dispositions in consumption patterns and competitive or conspicuous consumption (see Southerton and Ulph, 2014).

Environmental and ecological economics address macrolevel issues within the SPC research agenda. Ecological economics addresses the systemic relationships between economic systems and ecosystems. Environmental economics studies the economics of environmental policies, offering insights into a range of issues such as the valuation of consumption and capital assets from an environmental perspective (*see* Sustainable Development: An Economic Perspective), for example, using 'shadow prices' rather than market prices to make valuations including natural capital (see Southerton and Ulph, 2014). The emerging area of New Economics draws on these heterodox approaches to develop an alternative economic paradigm for SPC. The field addresses topics such as the drivers and effects of unsustainable consumption, the economics of well-being, grassroots socioeconomic innovations, and the macroeconomics of sustainability (such as issues of degrowth and steady state economics) (see Cohen et al., 2013).

Further major theoretical developments within SPC that have generated new questions and insights are found in the development of novel conceptual frameworks for production–consumption systems and in the reconceptualization of consumption. Conceptualizations of consumption are grounded in fundamental assumptions about human nature, connected to deep philosophical issues about the causes of human behavior (Wilk, 2002). The field thus reflects controversies within the social and behavioral sciences more broadly, and brings some of the key conceptual debates, over, for example, human agency and the relation between social and material phenomena, to the fore.

Processes of appropriating resources from the environment have for most of the modern era conventionally been ascribed to the sphere of production. Their ascription to the sphere of consumption in addition is a foundational innovation of SPC. However, consumption must be distinguished conceptually to avoid conflation with production, overall economic activity, other categories of environmental concern such as population or technology, or normative categories such as materialism (Princen, 1999).

Princen (1999) suggests that there are two fundamental approaches to the issue of sustainable consumption. The first is to work within the production–consumption, supply–demand, producer–consumer dichotomy, which does not debar examining product use and nonmarket activity. The second is to

challenge that dichotomy. Developments in the conceptual framework of SPC have navigated between these two fundamental positions. Princen (1999) acknowledges that both approaches have their limitations but argues for an ecologically grounded definition of consumption as 'material provisioning,' transcending the traditional dichotomy while maintaining the specificity of consumption as an analytical category. This is to treat all resource use (including that traditionally ascribed to production) as consumption or the using up of materials and energy in purposive human activity. Conventional approaches to SPC, such as LCA, often adopt versions of this position. Arguably, however, they have done so in a manner that lacks insight into the specific dynamics of use and demand, and consequently the importance of the latter for production–consumption systems over all.

In the first social science collection addressing sustainable consumption, Cohen and Murphy (2001), the editors, argued against Princen's position, suggesting that the physical dimension of material provisioning occludes the sociocultural dimensions of consumption. Material provisioning, they argued, ignores the phenomenology of consumption and its socially constructed aspects, including the social construction of the notion of the environment itself, and its role in policy formulation. Leaving aside whether this criticism is justified, this approach brings to the topic of sustainable consumption questions of meaning, identity, and communication in consumption associated with 'the cultural turn' in the social sciences. Cohen and Murphy (2001) here define consumption as people's acquisition (not necessarily through the market) and use of objects, services, and places, specifically excluding forms of institutional consumption (Cohen and Murphy, 2001: p. 8).

Shove and Warde (2002), however, criticized this cultural theory approach as offering limited analytical purchase to the routine, nondeliberative and 'inconspicuous' aspects of environmentally significant consumption. The reaction against the 'cultural turn' sought to move beyond the emphasis on consumer choice and changing lifestyles to a focus on social practices, the socially structured character of consumption and its mediation through infrastructures of provision, or the sociotechnical organization of consumption (see Southerton et al., 2004).

Warde reconceptualized consumption as "not itself a practice but…rather, a moment in almost every practice" (2005: p. 137), accommodating both the semiotic and utilitarian functions of consumption. Sustainability here chiefly relates to the way in which resources are appropriated in the pursuit of social practices. The practice perspective explores phenomena normally concealed to cultural analysis, including the temporal ordering of practices, the coevolution of social and technical systems, and the dynamics of sociotechnical change. Theories of practice, furthermore, have a particular affinity to sustainable consumption: offering explanatory resources for the use of goods and services in the accomplishment of everyday routine tasks (e.g., showering or commuting) and the role of the dynamics of social practices in escalating demand (see Welch and Warde, 2015). While in principle the productive sphere is equally amenable to practice theoretical accounts, thus far within SPC research practice theory has generally been applied to microsociological accounts of end use consumption.

A further key innovation is the multilevel perspective (MLP) on sociotechnical transitions, which has offered SPC a framework with which to analyze innovation and change in production–consumption systems. MLP offers a heuristic framework that distinguishes between levels of niche (where technical and social innovations form), sociotechnical regime (or incumbent production–consumption systems), and landscape (or broad cultural and historical context) (see, e.g., Elzen et al., 2004). MLP has also focused attention on the importance of intermediary levels between production and end-use consumption. While practice theoretical accounts have tended to neglect the productive sphere, MLP accounts have arguably lacked sophistication in their approach to consumption. The emerging pragmatic synthesis between practice theory and MLP therefore represents an important contemporary development within SPC (see Cohen et al., 2013; McMeekin and Southerton, 2012).

Considerations of the environmental impact of production have traditionally privileged the material perspective, while considerations of consumption have traditionally been formulated in normative terms. The main contributions of SPC research have therefore been to consider the environmental impacts of production also as social phenomena and to address the sustainability of consumption patterns as an object of social scientific enquiry. The promise of SPC research is to offer insights into the complex, systemic linkages between social, natural, and technical phenomena; how these systems change; and what possibilities for guiding that change we might be afforded.

This article is reproduced from the previous edition, volume 22, pp. 15335–15339, © 2001, Elsevier Ltd., with revisions made by the Editor.

Abstract

Sustainable transportation applies the concept of sustainable development to the movements of people and goods. Sustainable development requires that in meeting their own needs, generations must not compromise the ability of future generations to meet their needs. How to apply this to a single sector of society is unresolved, yet sustainable transport is clearly a necessary condition for societal sustainability. Motorization, concentrated in industrialized economies during most of the twentieth century, is rapidly globalizing. Transportation depends on petroleum for energy, yet half of total resources of conventional petroleum will have been consumed by 2025. Transition to alternative energy sources will be essential. Transportation is a major source of air pollution and noise. Since 1960, emissions per kilometer have been reduced but in many cities, the rate of traffic growth exceeds that of improving emissions controls. Solid waste from parts, fluids, scrapped vehicles, and infrastructure may require full recycling. Many consider the toll of deaths and injuries in accidents a sustainability issue. Transportation systems affect habitats directly, yet indirect effects on settlement patterns may pose the most difficult challenge. Equity requires increasing mobility in developing economies and for the less advantaged in general. How to measure progress toward sustainable transport is a key, unresolved issue.

The concept of sustainable transportation applies the idea of societal sustainability to a particular area of human activity: the movement of people and goods. Sustainability, or sustainable development, has been adopted by the United Nations agencies as an overarching goal of economic and social development (UNCED, 1992). Although there are several alternative definitions of sustainability, the most widely cited definition and the one generally recognized as initiating the global consideration of the subject, is that of the World Commission on Environment and Development (also known as the Brundtland Commission).

> Sustainable development is development that meets the needs of the present without compromising the ability of future generations to meet their own needs.
>
> (WCED, 1987, p. 43).

This and most other definitions constitute a normative concept of intergenerational responsibility or fairness. It is also significant that the context of the Brundtland definition was the issue of economic development and resulting conflicts with the environment. The concept of sustainability balances the right of less advantaged nations to economic development, with the imperative to preserve the resources, especially the environmental resources, that future generations will need for their own well-being. Thus, a concept of equity, both intergenerational and international, has been inherent in the idea of sustainability since its inception.

Sustainability pertains to the responsibility of an entire generation of society to future generations; whether it can meaningfully be applied to a single area of human activity such as transportation has been a subject of debate. That is, sustainability must be satisfied by the integral activities of a society and so, in this sense, it is not possible to judge whether one sector of society is sustainable on its own. On the other hand, it would not be possible for society to achieve sustainability, at least not in the long run, if even one sector were not sustainable. Thus, sustainable transportation may be considered a necessary but not sufficient condition for the sustainability of society.

Economic development has been central to the issue of sustainability since its inception. Economists have argued that the Bruntland definition implies non-decreasing well-being, and some have suggested that measures such as gross domestic product or real consumption per capita may be appropriate measures of sustainable growth. Others argue that well-being must be defined more broadly to include other areas of human development, such as education, health, environmental quality, and social justice (e.g., Pearce et al., 1994). In this broader view, the human institutions passed from one generation to another are just as important a resource as any other institution.

The question of how to translate the Brundtland imperative into a measurable and verifiable concept is still being worked out. In the economic literature, efforts to resolve this question have revolved around the concepts of weak and strong sustainability. The doctrine of weak sustainability holds that manufactured capital (machinery, buildings, infrastructure, etc.) is perfectly substitutable for natural capital (natural and environmental resources). This view holds not only that manufactured capital can be substituted for resources such as coal or iron ore, but that it can be substituted for environmental functions such as the ability of the air to absorb pollution or even the atmospheric and ocean processes that produce the global climate. Strong sustainability, on the other hand, maintains that there are limits to the substitutability of manufactured and natural capital. In particular, it maintains that there are certain environmental processes and functions that must be protected and preserved because they cannot be replaced by created capital. Ecosystems and biodiversity are often-cited examples of irreplaceable environmental processes.

How economic growth and expanding human welfare could continue indefinitely in the face of intensifying environmental impacts and finite natural resources is a central

question for theorists and researchers. Human activity, and especially economic activity, are inextricably linked to the environment by the ever-expanding quantities of natural resources extracted, processed and consumed (Pearce and Warford, 1993). Because mass and energy must be conserved due to the laws of nature, all the resources and energy used must end up somewhere in the form of waste (unless recycled). A useful way to conceive of the relationship between human activity and the environment is to imagine a coefficient of environmental intensity that relates total environmental damage to the total level of activity, perhaps measured, albeit incompletely by gross domestic product. Similarly, one can imagine a coefficient of natural resource requirements for input to the world economy. Because emissions controls, recycling, and greater energy efficiency can change the environmental coefficient, technological change and behavioral change clearly must play a key role in achieving sustainability. If the environmental coefficient can be reduced as fast or faster than the growth of human activity, and if increasing efficiency and recycling can similarly reduce the requirements for energy and other natural resource inputs, then it should be possible for human well-being to expand in a sustainable way.

The above line of reasoning identifies sustainability not as an equilibrium or final state of being able to continue indefinitely, but as a steady state in which the rate of improvement exceeds the rate of exhaustion of manufactured capital, natural resources, environmental services, and human and institutional capital. In this view, sustainability requires reducing demands on the environment per unit of activity as fast as or faster than the growth in activity. It requires increasing the efficiency of energy and resource use, or expanding the scope of useful resources at a rate at least as fast as the growth of human activity. It may even be interpreted more broadly as a matter of improving human institutions faster than challenges emerge to threaten them. While these concepts can and have been applied to transportation, a comprehensive theory of sustainable transportation that is measurable and verifiable is still yet to emerge.

Sustainable Transportation and Economic Development

Throughout history, the expansion and improvement of transportations systems has been an engine of economic development (Greene and Wegener, 1997). The fast and reliable movement of persons and commodities contributes more than simply a reduction in the costs of production. It facilitates the reorganization of production and consumption to permit specialization, scale economies, inventory reduction, and more. Today, transportation activity continues to increase at roughly the rate of economic growth in both the developed and developing economies.

Motorized transport is the source of essentially all the demands transportation imposes on natural and environmental resources. The motorization of transport, fully accomplished in the developed economies during the twentieth century, is now proceeding rapidly in the developing world. In 1950, 90 percent of the world's 50 million motor vehicles could be found in Europe or the United States. Today, half of the world's roughly 700 million vehicles are to be found outside of those countries. The developing economies own more than one-third of the world's motor vehicles, and vehicle ownership outside of the developed economies is growing at twice the rates seen in the developed economies. The global potential for motorization is enormous. In developed economies, motor vehicle ownership rates average 500 per 1000 persons. In the US, there is more than one motor vehicle per person of driving age. Ownership rates in the developing economies are about one-twentieth as high.

Expansion of modern, motorized transportation in the developing economies appears to be essential to their sustainable development. The World Bank has identified three broad types of sustainability in considering transport investments in developing countries: (1) economic and financial sustainability; (2) environmental sustainability; and, (3) social sustainability (World Bank, 1996). These categories reflect the view that to be sustainable, transportation systems must have stable financing in the context of market economies, must address the many adverse impacts of transportation on health and ecosystems, and must serve the mobility needs of the poor as well as those with the ability to pay.

Environmentally Sustainable Transport

Transportation systems have diverse and widespread impacts on the environment, affecting climate, air and water quality, noise, habitats, and biodiversity. Worldwide, transportation accounts for one-fourth of global carbon dioxide emissions. Scientists have concluded that the accumulation of carbon dioxide and other less common anthropogenic greenhouse gases in the world's atmosphere since the onset of the industrial revolution are now having a perceptible impact on the earth's climate. While it is not yet clear what the impacts on climate will be, they are likely to include increases in storm activity, changes in the patterns of rainfall, a general warming leading to higher sea levels, and other potentially harmful or even catastrophic effects. The quantity of carbon dioxide emission produced by transportation depends on the carbon content of the transportation fuels and the energy efficiency of transport systems. Today, motorized transport is entirely dependent on fossil fuels. The combustion of fossil fuels is the predominant source of greenhouse gas emissions from human activities. A typical passenger car adds 1 to 2 tonnes of carbon to the atmosphere each year. Despite 50–100 percent increases in the fuel economy of automobiles over the past 30 years, there appears to be no prospect of reducing global greenhouse gas emissions from transportation for at least 20 to 30 years. Clearly, continuing to force alterations in the earth's climate systems in unpredictable ways does not satisfy the sustainability doctrine.

Transportation is a major source of local and regional air pollution. In Europe and the United States, transportation vehicles emit roughly 45 percent of nitrogen oxides and 40 percent of volatile organic compounds that mix in the atmosphere to form ozone, a pollutant that exacerbates a variety of respiratory problems and causes damage to vegetation as well. Air pollutants from transport have an immediate impact on human health and on vegetation. Ozone pollution has been

observed to change the distribution of tree species in forests, retard the growth of vegetation, and damage crops. Prolonged exposure to ozone is strongly believed to reduce biodiversity of plant communities and diminish variability in their gene pools (NRC, 1997). Emissions of oxides of nitrogen and sulfur from motor vehicles contribute to acid rain with widespread negative impacts on terrestrial and aquatic ecosystems. Volatile organic compounds also include a number of toxic pollutants, including known and suspected carcinogens, such as benzene, formaldehyde, cyanide, and dioxin.

Transportation vehicles produce significant quantities of fine particulate pollution via several mechanisms. Vehicle tailpipe emissions contain particles produced by incomplete combustion. Particles and aerosols are formed when certain motor vehicle emissions react in the air. Finally, dust from roads is a major source of air-borne particulate matter. Fine particulate matter can be inhaled deeply into the lungs, contributing to a variety of respiratory problems. Epidemiological studies have correlated elevated morbidity and mortality rates with long-term, low-level exposure to fine particulates, as well as to episodes of acute pollution, suggesting that particulate pollution may be the most serious form of motor vehicle pollution from the perspective of human health (NRC, 1997).

Since the 1950s, enormous technological progress has been made in reducing the pollutant emissions from new transportation vehicles. A properly operating motor vehicle manufactured in 2000 produces 1 percent to 10 percent of the pollution (depending on the pollutant) of a car made 35 years earlier. Still, even this rate of progress has been insufficient to achieve air quality standards in many urban areas because the growth of travel has outpaced the rate of technological improvement. Further significant improvements in conventional vehicles and fuels will be made from 2000 to 2010. Yet achieving sustainability will probably require entirely new energy sources and propulsion technologies ultimately.

Solid Waste

Transportation infrastructure and vehicles generate enormous amounts of solid waste. Some of this waste, such as iron and steel, has a long history of recycling. Other components like plastics most often end up in landfills or incinerators. Waste oil and fluids, batteries, and other components often contain toxic materials that pose serious health and environmental hazards if not properly disposed of. The maintenance and reconstruction of transportation facilities also generate substantial quantities of mostly asphalt and concrete waste. Not only increased recycling, but life-cycle management of materials for transportation systems has been recognized as essential to achieving sustainable transportation systems (OECD, 1997).

Noise

It may seem odd to include noise among the issues affecting transportation's sustainability. Noise, after all, is inherently transitory and its impacts on society and the environment would seem to be also. On the other hand, transportation systems operate more or less continuously, generating noise around the clock. Studies carried out in Europe have shown that about 20 percent of the population are exposed to daytime transport noise exceeding acceptable levels (65dB(A)) (European Commission, 1995). Another 170 million are exposed to noise levels that cause serious annoyance as defined by the World Health Organization. Road noise is the dominant source, followed by rail and air transport. Furthermore, data for the 1980–95 period showed no significant improvement in exposure to traffic noise for the population of Europe. The principal impacts of transportation noise are annoyance, interference with work and sleep and, less commonly, hearing loss. Estimates of the costs of noise pollution in Europe range between 0.1 percent and 2 percent of GDP.

Natural Resources

Transportation is a major consumer of two critical, limited resources: land and petroleum. Worldwide, transportation accounts for 56 percent of global petroleum consumption and between 1973 and 1997 was responsible for all of the increase in world oil consumption (IEA, 2000). Recent assessments of the world's supplies of conventional petroleum indicate that sometime between 2005 and 2025, the world will have consumed half of all the conventional petroleum that is known or believed to exist (EIA, 2000 and USGS, 2000). Once this point is passed, it is virtually certain that production of conventional petroleum will begin to decline, and unconventional energy sources will have to be substituted at an increasing rate. The world's transportation system, which is 97 percent dependent on petroleum for energy, will not be sustainable unless it can make a transition to alternative energy sources. While there are more than adequate resources of fossil fuels that can be converted to transport fuels (e.g., coal, oil shale, and tar sands), the greater environmental impacts associated with using these fuels raises serious questions about the sustainability of a motorized world transport system based on fossil fuels.

Perhaps even more serious are the questions raised by transportation systems' expanding direct and indirect uses of land. Not only does transportation infrastructure such as road, airports, and railroad tracks, occupy millions of hectares of land, but the infrastructure and vehicles that use it have significant impacts on surrounding ecosystems. Linear transportation structures serve as deadly barriers to the migration and movements of species, and alter water flow and groundwater. But perhaps more importantly, transportation infrastructure indirectly alters the patterns and density of human settlements, with even more pervasive impacts on ecosystems and biodiversity (NRC, 1997).

Sustainable Communities

Transportation is recognized as a key element of sustainable communities (PCSD, 1997). Human development patterns and the transportation systems that serve them are strongly interdependent. Transportation choices made by present generations will constrain the opportunities of future generations because

built environments can be changed only slowly and at great cost. The high level of mobility provided by automotive transport has engendered dispersed low-density development, sometimes referred to as sprawl. The area of built-up urban land in the United States increased by an estimated 14 million acres between 1982 and 1992, driven in large part by the expansion of highway infrastructure (BTS, 1996, p. 162).

As demand for mobility has continued to grow, while the land available for expanding transportation infrastructure in urban areas has not, chronic congestion has become a major problem in cities around the world. Increasing levels of traffic congestion are not only a source of stress and waste the time of present generations, but can restrict the opportunities for mobility of future generations. If the capacities of transportation systems cannot be expanded to accommodate future growth without incurring unacceptable trade-offs, the options available to future generations will be diminished.

Safety

Safety must also be included in assessing the sustainability of transportation systems (e.g., Black, 2000). While absolutely compelling as a human tragedy, the sense in which transportation safety is a sustainability issue may be less obvious. Globally, there are about 700 000 motor vehicle fatalities annually, and many millions of serious injuries. On the other hand, fatality rates (e.g., per 100 000 vehicle miles) are generally declining. In developed economies such as the United States, recent years have seen declines in total fatalities even while motor vehicle travel and population size continue to grow. In countries undergoing rapid motorization, however, total fatalities are increasing at the same time rates are declining. When both fatalities and fatality rates are increasing, the sustainability of transportation systems is in question. The resource at issue is human life itself, and the needs of future generations would clearly appear to be threatened by increasingly unsafe transportation systems. Where both total fatalities and fatality rates are declining, an argument can be made for sustainability. Without a doubt, safety is the single most important problem facing transportation. Yet, to date there is little agreement on how safety should be interpreted in the context of the sustainability doctrine.

Equity

Equity among generations is clearly integral to the concept of sustainability. For sustainability to exclude equity considerations among individuals within a generation would be inherently inconsistent. The Charter of European Cities and Towns Towards Sustainability states that the goals of sustainable development are '… to achieve social justice, sustainable economies, and environmental sustainability' (Greene and Wegener, 1997). Furthermore, the context of the Brundtland sustainability definition was clearly the need to preserve the global environment while permitting developing countries the economic development that is their right. Clearly social justice and particularly equity have been integral to the concept of sustainability. It has been argued that the concept of intergenerational fairness embodied in sustainability, in fact arises from a societal commitment to equality of opportunity among contemporaries (Howarth, 1997). Exactly how equity concerns are to be incorporated in an operating definition of sustainability has yet to be resolved, as have the implications for transportation. At a minimum, equity considerations include the interests of developing economies to pursue higher levels of mobility, as well as the needs of disadvantaged citizens for access to mobility in all societies.

Measuring Sustainability

If policies are to be formulated and implemented to achieve sustainable transportation, indicators must be found to measure it (OECD, 1994). If the steady-state concept of sustainability is accepted, these indicators should show:

- whether the world's environmental resources are being reduced by transportation's impacts on air or water pollution;
- whether the global climate is being altered by greenhouse gas emissions;
- whether habitats are being destroyed through direct or indirect land-use impacts; and
- whether the generation of solid waste is increasing or being restrained by recycling.

Indicators must show whether the fundamental natural resources required for transportation, such as energy and land, are being expanded as fast or faster than they are being consumed, and whether transportation systems are being developed and managed so as to enhance social equity by improving access to mobility for all. Until the consequences of transportation for sustainability are made visible measuring them, progress toward sustainable transportation will be limited.

Editor's Note

Sustainable transportation continues to be be a concern of urban planners, transportation specialists, and environmentalists. Three recent books provide helpful updates to the themes, findings, and literature reviewed in Dr. Greene's original entry: Black, 2010; Schiller et al, 2010; Worrall, 2005.

Abstract

'Symbolic Boundaries' are the lines that include and define some people, groups, and things while excluding others. These distinctions can be expressed through normative interdictions (taboos), cultural attitudes and practices, and patterns of likes and dislikes. They play an important role in the creation of inequality and the exercise of power. The term 'symbolic boundaries' also refers to the internal distinctions of classification systems and to temporal, spatial, and visual cognitive distinctions in particular. This article focuses on boundaries within and between groups. It discusses the history, current research, and future challenges of work on this topic.

Definition and Intellectual Context

'Symbolic Boundaries' are the lines that include and define some people, groups, and things while excluding others (Epstein, 1992: p. 232). These distinctions can be expressed through normative interdictions (taboos), cultural attitudes and practices, and patterns of likes and dislikes. They play an important role in the creation of inequality and the exercise of power. The term 'symbolic boundaries' also refers to the internal distinctions of classification systems and to temporal, spatial, and visual cognitive distinctions in particular (Wagner-Pacifici, 2000; Zerubavel, 1997). This article focuses on boundaries within and between groups. It discusses the history, current research, and future challenges of work on this topic.

The literature on symbolic boundaries has gained importance since the 1960s due to a convergence between research on symbolic systems and indirect forms of power. Writings by Pierre Bourdieu, Mary Douglas, Norbert Elias, Erving Goffman, and Michel Foucault on this topic have influenced several disciplines internationally, particularly anthropology, history, literary studies, and sociology. In North America, a renewed cultural sociology has produced wide-ranging empirical research agendas on symbolic boundaries and inequality. In other fields including community, cognition, deviance, gender, immigration, knowledge and science, nationalism, professions, race and ethnicity, and social movements, boundaries issues have gained analytical prominence.

History

Two of the founding fathers of sociology played central roles in shaping the literature on symbolic boundaries: Emile Durkheim and Max Weber. We review their contributions before turning to the 'neo-classical' writings of Mary Douglas, Norbert Elias, and Thorstein Veblen, which illustrate the lasting influence of Durkheim and Weber on this literature up to the 1960s. While Durkheim emphasized classification systems and their relationship with the moral order, Weber emphasized their impact on the production and reproduction of inequality. (For a more encompassing historical overview, see Schwartz, 1981.)

One widely used example of symbolic boundaries is taken from Durkheim's work, *Les formes élementaires de la vie religieuse* (*The Elementary Forms of Religious Life*, 1965[1911]). Durkheim argues that the religious experience is distinct from other types of experiences because it involves a symbolic distinction between the realms of the sacred and the profane (pp. 234, 250). The meanings of these realms are mutually exclusive and are defined relationally, through interdictions and rituals that isolate and protect the former from the latter (e.g., a Roman-Catholic sinner cannot receive communion until he is purified through confession) (p. 271).

The distinction between the sacred and the profane extends to the whole universe of objects and people in which it takes place. For instance, the status of members of a community is defined by the types of relationship they have with sacred objects (e.g., Roman Catholic women cannot celebrate mass). In this sense, religious systems provide a cosmology, i.e., a general interpretation of how the world is organized and how its elements relate to one another and to the sacred. This cosmology acts as a system of classification and its elements are organized according to a hierarchy (e.g., counterposing the pure with the impure). The belief invested in this 'order of things' structures people's lives to the extent that it limits and facilitates their action.

Durkheim also points to the existence of a moral order (i.e., a common system of perception of reality that regulates, structures, and organizes relations in a community). This system operates less through coercion than through intersubjectivity (p. 238). In fact, Durkheim defines society by its symbolic boundaries: it is the sharing of a common definition of the sacred and the profane, of similar rules of conduct and a common compliance to rituals and interdictions that defines the internal bonds within a community. Hence, he posits that the boundaries of the group coincide with those delimiting the sacred from the profane.

Unlike Durkheim, Max Weber focuses on the role of symbolic boundaries (honor) in the creation of social inequality rather than social solidarity. In *Wirtschaft und Gesellschaft* (*Economy and Society*, 1922/1956), he describes human beings as engaged in a continuous struggle over scarce resources. To curb competition, they discriminate toward

various groups on the basis of their cultural characteristics, such as lifestyle, language, education, race, or religion. In the process, they form status groups whose superiority is defined in relation to other groups. They cultivate a sense of honor, privilege relationships with group members, and define specific qualifications for gaining entry to the group and for interacting with lower status outsiders (e.g., opposing miscegenation). They invoke their higher status and shared rules of life to justify their monopolization of resources. Hence, cultural understandings about status boundaries have a strong impact on people's social position and access to resources.

Thorstein Veblen's *The Theory of the Leisure Class* (1899/1979) parallels Weber's writings. This American economist suggests that habits of thought ('classifying and demarcating') are central to the mechanisms that produce boundaries between status groups, and they are often organized around notions of superiority and inferiority concerning employment, consumption, and leisure. For instance, idleness symbolizes status because it signifies pecuniary status. He writes, "refined tastes, manners, and habits of life are useful evidence of gentility because good breeding requires time, application, and expenses" (p. 49) and are therefore not available to those "whose time and energies are taken up with work." Veblen also developed the concept of 'conspicuous consumption.' He argues that the possession and display of wealth confers honor: as an invidious distinction, it symbolizes ranking within a group. This way of manifesting superiority is more common when predatory aggression or war are less frequent. Veblen's analysis assumes that there is a tendency to change standards of sufficiency as one's pecuniary situation improves; one becomes restless with creating 'ever-widening distance' between herself and the average standard.

Also paralleling Weber's work, is the work of German sociologist Norbert Elias. In *Über den Prozess der Zivilisation* (*The Civilizing Process*, 1982[1939]), Elias analyzes the emergence of a boundary between civilized and barbarian habits using evidence from Western manner manuals written between the late middle ages and the Victorian period. He examines 'natural' bodily functions such as spitting and defecating to demonstrate the growing centrality of shame and embarrassment in instituting norms of behavior in public and private over time. More broadly, he argues that standards of behavior and feelings and personality structures (what he calls 'habitus,' or habits emerging from social experience) vary across hierarchical groups in society and that these variations are key to pacification and the exercise of power. In a later study, *The Established and the Outsiders* (1965/1994, with John L. Scotson), Elias shows how residents of one part of a town, 'the Village' had higher status than residents of another part of the town, 'the Estate,' because the former had the social cohesion and resources to stigmatize the outsiders and impose their own definition of self.

To turn now to the lasting influence of Durkheim's work, in *Purity and Danger* (1966), Mary Douglas examines the order-producing, meaning-making and form-giving functions of classification systems and the role of rituals in creating boundaries grounded in fears and beliefs. In *Natural Symbols* (1970), she describes how the structure of binary symbolic systems reflects group structures. Like Elias, she also probes the moral order and focuses on the system of social control as expressed through the body and through observable artifacts of everyday life (food, dirt, and material possessions). She argues that the basis of order in social life is the presence of symbols that demarcate boundaries.

One of Douglas's main concerns is how communities differentiate themselves from one another and how they are internally differentiated. She distinguishes groups on the basis of their degree of social control and of the rigidity of their grid (i.e., the extent to which their system of classification competes with other systems). In societies with high social control and great cultural rigidity (i.e., what she calls high grid and group), there is a concern to preserve social boundaries; the role structure is clearly defined; and formal behavior is highly valued and well defined in publicly insulated roles. Through 'the purity rule,' formality screens out irrelevant organic processes.

Current Theory and Research

In the contemporary literature on symbolic boundaries, both the neo-Weberian and neo-Durkheimian heritage remain strong. The question of how boundaries intersect with the production of inequality has attracted interest since the publication of Pierre Bourdieu's impressive corpus. In the United States, cultural sociologists have assessed Bourdieu's theoretical claims and used his work to illuminate the cultural aspects of class, gender, and racial inequality. Other developments concern the study of identity through boundary work, and research on moral order, community, symbolic politics, and religion. While some of this research is reviewed in Pachucki et al. (2007) and in Lamont (2012), the discussion below considers new contributions as well as less recent ones.

Culture and Inequality

In the last 30 years, a large neo-Weberian literature emerged about processes of closure. Frank Parkin (1979) drew on Weber to study the distributive struggle for monopolizing or usurping resources within and across classes. He emphasized the right of ownership and credentialism, i.e., the use of educational certificates to monopolize positions in the labor market. Equally inspired by Durkheim, Collins (1998) extended his earlier work on credentialism and interaction rituals to analyze how intellectuals compete to maximize their access to key network positions, cultural capital, and emotional energy, which generates intellectual creativity. These contributions coincide with those of Pierre Bourdieu and his collaborators.

In *Reproduction* (1977[1970]), Pierre Bourdieu and Jean-Claude Passeron proposed that the lower academic performance of working-class children cannot be accounted for by their lower ability but by institutional biases. They suggest that schools evaluate children based on their familiarity with the culture of the dominant class (or cultural capital), thus penalizing lower-class students. Extensive vocabulary, wide-ranging cultural references, and command of high culture are valued by the school system and students from higher social backgrounds are exposed to this class culture at home. Lower-class children remain under the spell of the dominant class culture. They blame themselves for their failure, and

consequently drop out or sort themselves into lower prestige educational tracks.

This work extends Karl Marx and Friedrich Engels' (1848/1960) 'dominant ideology thesis,' which centers on the role of ideology in cementing relations of domination by camouflaging exploitation and differences in class interests. However, Bourdieu and Passeron are more concerned with classification systems than with representations of the social world itself, i.e., with how representations of social relationships, the state, religion, and capitalism contribute to the reproduction of domination. Implicitly building on Gramsci (1971), they focus on the control of subjectivity in everyday life through the shaping of common sense and the naturalization of social relations. They broaden Marx and Engels by suggesting that crucial power relations are structured in the symbolic realm proper, and are mediated by meaning. They *de facto* provide a more encompassing understanding of the exercise of hegemony by pointing to the incorporation of class-differentiated cultural dispositions mediated by both the educational system and family socialization.

In *Distinction* (1984[1979]), Bourdieu applies this analysis to the world of taste and cultural practice at large. He shows how the logic of class struggle extends to the realm of taste and lifestyle, and that symbolic classification is key to the reproduction of class privileges: dominant groups define their own culture as superior. Thereby they exercise 'symbolic violence,' i.e., impose a specific meaning as legitimate while concealing the power relations that are the basis of its force (Bourdieu and Passeron, 1977[1970]: p. 4). They define legitimate and 'dominated' cultures in opposition: the value of cultural preferences and behaviors are defined relationally around binary oppositions (or boundaries) such as higher/lower, pure/impure, distinguished/vulgar, and aesthetic/practical (p. 245). The legitimate culture they thereby define is used by dominant groups to mark cultural distance and proximity, monopolize privileges, and exclude and recruit new occupants to high status positions (p. 31). Through the incorporation of '*habitus*' or cultural dispositions, cultural practices have inescapable and unconscious classificatory effects that shape social positions.

A large American literature applying, extending, assessing, and critiquing the contributions of Bourdieu and his collaborators developed in the wake of their translation in English (for an early review, see Lamont and Lareau, 1988.) For instance, DiMaggio (1987) suggests that boundaries between cultural genres are created by status groups to signal their superior status. DiMaggio and Mohr (1985) found that levels of cultural capital influence higher education attendance and completion as well as marital selection patterns in the United States. Lamont (1992) critiqued Bourdieu (1984) for exaggerating the importance of cultural capital in upper-middle-class culture and for defining salient boundaries a priori, instead of inductively. Based on interviews with professionals and managers, she showed that morality, cultural capital, and material success are defined differently and that their relative importance vary across national contexts and by subgroups. Lamont also showed variations in the extent to which professionals and managers tolerate the lifestyles and tastes of other classes, and argued that cultural laissez-faire is more important in American society than French society. High social and geographic mobility, strong cultural regionalism, ethnic and racial diversity, political decentralization, and relatively weak high culture traditions translate into less highly differentiated class cultures in the United States than France (also see Lamont, 2010).

Other sociologists also argue that cultural boundaries are more fluid and complex than cultural capital theory suggests. Hall (1992) emphasized the existence of heterogeneous markets and of multiple kinds of cultural capital. He proposes a 'cultural structuralism' that addresses the multiplicity of status situations in a critique of an overarching market of cultural capital. Crane (2000) analyzes how social change disrupts the relationship between cultural capital and social class strata during nineteenth- and twentieth-century France and the United States. In separate studies of visual art consumption, Halle (1993) and Banks (2009) show how meanings attached to artwork in the home are influenced by factors afield of class. For Halle's participants, art consumption does not necessarily generate social boundaries, and he finds that the meaning attached to living room art is somewhat autonomous from professional evaluations. Banks explores how middle-class blacks feel they contribute to black cultural advancement through patronage of black artists and cultural institutions. Pachucki (2012) explores how art professionals make symbolic distinctions in their everyday work with art, and shows how these boundaries shape status hierarchies across museums. Lareau (2003) analyzed how middle- and working-class parents socialize their children for middle- and working-class jobs. Researchers have continued to provide a more complex approach to cultural capital through ethnographies of how teenagers learn status and privilege in elite boarding schools (Gaztambide-Fernandez, 2009; Khan, 2011) and an ethnography of hiring practices in elite professional firms (Rivera, 2012).

Research on cultural omnivorousness suggests that cultural breadth is a highly valued resource in the upper and upper-middle classes, countering Bourdieu's postulate that the value of tastes is defined relationally through a binary or oppositional logic between upper- and lower-class cultures. Studies of musical tastes (Bryson, 1996; Peterson and Kern, 1996; Peterson and Rossman, 2008), familiarity with popular culture (Erickson, 1996), arts participation (Alderson et al., 2007; DiMaggio and Mukhtar, 2004), and food consumption (Johnston and Baumann, 2010) are among a growing body of scholarship that highlights the complexities of how individuals distinguish themselves through the diversity of what they consume. Lena's (2012) work on music genres suggests that aesthetic boundaries are only one element in a complex interplay with audiences and industry forces. Her careful analysis shows how types of music share similar trajectories in their emergence and transformation.

Identity and Boundary Work

The literature on identity is another arena where the concept of symbolic boundaries has become more central. Sociologists and psychologists have studied boundary work, a process central to the constitution of the self. Thomas Gieryn originally proposed the concept of boundary work in the early 1980s to designate "the discursive attribution of selected qualities to scientists, scientific methods, and scientific claims for the

purpose of drawing a rhetorical boundary between science and some less authoritative residual non-science"(1999: pp. 4–5). Since then, sociologists have analyzed this process by looking at self-definitions of ordinary people and in a range of contexts beyond science.

Social psychologists working on group categorization have studied the segmentation between 'us' and 'them.' Brewer's (1986) social identity theory suggests that "pressures to evaluate one's own group positively through in-group/out-group comparison lead social groups to differentiate themselves from each other." This process of differentiation aims "to maintain and achieve superiority over an out-group on some dimension" (Tajfel and Turner, 1985: pp. 16–17). While these authors understand the relational process as a universal tendency, sociologists are concerned with analyzing precisely how boundary work is accomplished, i.e., with what kinds of typification systems, or inferences concerning similarities and differences, groups mobilize to define who they are.

The study by Jenkins (1996) on social identity also contributes to the study of boundary work. He describes collective identity as constituted by a dialectic interplay of processes of internal and external definition. On one hand, individuals must be able to differentiate themselves from others by drawing on criteria of community and a sense of shared belonging within their subgroup. On the other hand, this internal identification process must be recognized by outsiders for an objectified collective identity to emerge. These insights continue the early efforts of Du Bois (1903) who emphasized the work of managing the 'color line' or 'veil' that defines race and of Barth (1969) who analyzed the process of ethnic boundary making. They also mirror work on racial group positioning (Blumer, 1958; Bobo and Hutchings, 1996).

During the 1990s, seminal studies of self-definitions among ordinary people emerged. For instance, Newman (1999) analyzes how poor fast-food workers define themselves in opposition to the unemployed poor. Lamont (1992) studies the boundary work of professionals and managers while Lamont (2000) examines how workers in the United States and France define worthy people in opposition to the poor, 'people above,' blacks, and immigrants, drawing moral boundaries toward different groups across the two national contexts. Lichterman (1999) explores how volunteers define their bonds and boundaries of solidarity by examining how they articulate their identity around various groups. These mappings translate into different kinds of group responsibility, in "constraining and enabling what members can say and do together." Binder (1999) analyzes boundaries that proponents of Afrocentrism and multiculturalism build in relation to one another in conflict within the educational system. Becker (1999) studies how religious communities build boundaries between themselves and 'the public.' Finally, Gamson (1992) analyzes how the injustice frames used in social movements are organized around 'us' and 'them' oppositions.

Studies of boundary work and identity continue to flourish in the fields of race and ethnicity and immigration. For instance, Carter (2005) examines the diverse ways black and Latino youth manage ethnic boundaries in school and their peer groups and the consequences for their academic achievement. Warikoo (2011) analyzes how second-generation Indo-Caribbean teenagers negotiate ethnic boundaries in London and New York and the role of hip-hop and other aspects of youth culture. Wimmer and Lewis (2010) use Facebook data to explore how racial homogeneity in Americans' social networks is linked with social stratification. Other scholars have considered the relationship between racial and class boundaries. Young (2006) focuses on the ways poor black men think about status mobility and opportunity. Lacy (2007) analyzed the boundary work of race and class among blacks across different types of middle-class neighborhoods. Pattillo (2007) considers boundaries between middle-class and poor blacks in a mixed income neighborhood and how they are negotiated as neighborhood residents promote black political action. In the area of immigration and ethnicity, Alba (2009) and Wimmer (2013) have focused on group formation processes. Also, Roth (2012) analyzes how migration and transnationalism influence definitions of panethnic identity among Puerto Ricans and Dominicans. Future research on the process of collective identity formation may benefit to focus on the dynamic between self-identification and social categorization.

Moral Order, Community, Symbolic Politics, and Religion

A third strand of work on symbolic boundaries presents more palpable neo-Durkheimian influences. Several studies have centered on moral order and on communities. Wuthnow (1987: p. 69) writes, "Order has somehow to do with boundaries. That is, order consists mainly of being able to make distinctions – of having symbolic demarcations – so that we know the place of things and how they relate to one another." A recent example of this neo-Durkheimian line of work is Alexander's (1992) semiotic analysis of the symbolic codes of civic society. The author describes these codes as "critically important in constituting the very sense of society for those who are within and without it." He also suggests that the democratic code involves clear distinctions between the pure and the impure in defining the appropriate citizen. His analysis locates those distinctions at the levels of people's motives and relationships, and of the institutions that individuals inhabit (with 'honorable' being valued over 'self-interested' or 'truthful' over 'deceitful' in the case of the democratic code).

The last decades have produced studies of status politics that documented how groups sharing a lifestyle made such distinctions, engaged in the maintenance of the moral order, and simultaneously bolstered their own prestige. Particularly notable is Gusfield (1963) who analyzed the nineteenth-century American temperance movement in favor of the prohibition and the Eighteenth Amendment to the constitution. Gusfield understands this movement as a strategy used by small-town Protestants to bolster their social position in relation to urban Catholic immigrants. Along similar lines, Luker (1984) describes the worldviews of antiabortion and pro-choice activists. She shows that they have incompatible beliefs about women's careers, family, sexuality, and reproduction, and that they talk past one another and define themselves in opposition to one another. Beisel (1997) has studied Anthony Comstock's nineteenth-century antipornography movement to protect the morality of children in the context of important social changes that threatened the reproduction of upper class privileges. However, she argued against the distinction between

symbolic and class politics and showed how the two often operate hand in hand, particularly in the drawing of moral boundaries. The literature on social movements includes studies that focus on the process by which categories of people are turned into categories of enemies (Jasper, 1997). Using the case of the 11 September attacks, Wagner-Pacifici (2010) also advanced a 'political semiosis' methodology for understanding the bounding and unbounding of events.

Scholars recently have shown how symbolic boundaries play a key role in issues around religious identification. Bean et al. (2008) offer a comparative-historical investigation of how Canadian evangelicals mobilize around moral issues, finding that in both Canada and the United States, political identification, beliefs, and religious group membership evolve in a path-dependent process. Religious boundaries and everyday interactions intersect for Tavory (2010), who explores how members of an Orthodox Hassidic group in Los Angeles signal Jewish identification. Yukich (2010) focuses on how the Catholic Worker movement, which considers itself inclusive, constructs exclusionary boundaries against other service and charitable organizations. For their part, Edgell and Tranby (2010) investigate how various types of sub-group identity relates with a shared American identification. They find three types of citizen that they term 'cultural preservationists,' 'critics of multiculturalism,' and 'optimistic pluralists.' Also, Edgell and Gerteis (2006) identify atheism as a salient group boundary in the United States.

Challenges and Future Directions

A persistent challenge since the emergence of this field of scholarship is understanding the connection between objective boundaries and symbolic boundaries. As Lamont (1992) argued, symbolic boundaries are a necessary but insufficient condition for the creation of objective boundaries. Early research on objective social boundaries focused on topics such as the relative importance of educational endogamy versus racial endogamy among the college-educated (Kalmijn, 1991); racial hiring and firing (Silver and Zwerling, 1992); residential racial segregation (Massey and Denton, 1993); the relative permeability of class boundaries (Wright and Cho, 1992); and the creation of professional boundaries (Abbott, 1988). Tilly (2004) provides a synthesis of social boundary mechanisms. More recent theoretical consolidation has contributed to our understanding of links between symbolic and social boundaries. Lamont and Molnar (2002) issued a challenge to find similarities of boundary configurations across cases. These efforts have been extended to the study of ethnicity and race (see special issue of *Poetics*, Pachucki et al., 2007), immigrant and national identity (Zolberg and Woon, 1990; Bail, 2008; Rivera, 2008; Wimmer, 2013; Brubaker, 2009), evaluation processes (Lamont, 2012), and responses to stigmatization (see special issue of *Ethnic and Racial Studies*, Lamont and Mizrachi, 2012 and the special section of the *Du Bois Review*, Lamont et al., 2012).

Symbolic Interaction: Methodology

Andrea Fontana, University of Nevada Las Vegas, Las Vegas, NV, USA

This article is reproduced from the previous edition, volume 23, pp. 15347–15350, © 2001, Elsevier Ltd, with revisions made by the Editor.

Abstract

This article first introduces the origins of symbolic interactionism (SI) and its early methodological developments. It then discusses the more recent influence of postmodernism on the methodological orientations of SI. It ends with a survey of recently developed methods of SI. It argues that recent methods diverge from Blumer's initial guiding ideas drastically, but the diversity among them may be exaggerated.

This article will examine the different types of methodology used by Symbolic Interactionism. The bulk of the contribution will outline Blumer's qualitative approach, based on Mead's theories. Blumer coined the term symbolic interaction and suggested participant observation as the preferred method to study interaction. The article will also discuss briefly the method attempted by the Iowa School of Symbolic Interactionism, which was psychologically based. Finally, it will outline the new postmodern-informed, interactionist method used by a growing number of symbolic interactionists led by Denzin. Mention will be made of radical interactionist methods suggested by Ellis, Clough, and Richardson, among others.

The term 'symbolic interactionism' (SI) was coined in an article by Blumer (1937). SI presented a radical break from the traditional, macrostructural theories of sociology. SI rejected the scientific method and its reliance on predetermined hypotheses. SI's goal was not predicting about society, as structuralist methodologies did, but understanding the nature of the social world. In basing its research in the real world of everyday life, SI relied heavily on the theoretical work of the pragmatists, especially that of Mead (1934).

Blumer and Naturalistic Research

In his book containing reprints of his earlier articles, Blumer (1969) applies a methodology, naturalistic research, to the theoretical work of Mead. In symbolic interactionism, theory and methodology are intertwined very closely. Mead's social pragmatism advocated a study of society that takes place in small group interaction; namely, the relation of self and others. This reciprocal interaction is derived, for Mead, through the use of symbols, primarily language but others as well. Thus, society, for Mead, is a consensual, intersubjective world where the sharedness of meanings among its members allows some stability in an ever-changing flux (cf Adler and Adler, 1980).

Blumer, who was first a student and then a colleague of Mead at the University of Chicago, followed the latter's theoretical ideas and stated that society exists in action, in the reciprocal exchange of symbols, and the meaning these have for the members of society. If society is to be found in the interactional processes of its members we should study it in 'the real world,' i.e., the world created by societal members in their interaction, rather than in artificial settings or hypothetical situations. For Blumer, it follows that rather than constraining the study of social processes with controlled variables we should proceed with minimal intervention by the researcher. Also, in trying to maintain the integrity of the phenomenon under investigation we should not fit the 'real world' to our method, as typical in survey research, but should adapt out methodology to the world and thus use flexible data collection strategies. Finally, the model of the study should not be predetermined and then tested, but should be ever-changing to fit the changes and events in the real world.

For Blumer the naturalistic research has two phases: exploration and inspection. Exploration allows the researcher to gain a clearer understanding of the study, what methods to use, and to conceptualize the area of study in order to be able to talk from facts rather than speculations (Blumer, 1969). Exploration should be flexible and change as necessary to understand the topic at hand and thus should rely on a multiplicity of methods including observation, interviewing, life histories, and personal documents. Exploration is the first step of naturalistic inquiry for Blumer but must be complemented by another, more analytic step, inspection. This latter step aids the researcher in developing an analytic understanding of the elements of inquiry and their relations. This understanding is sensitizing rather than definitive, as the world studied is a process, i.e., ever changing. Furthermore, inspection allows for the testing of theoretical propositions. Thus, naturalistic research uses exploration to define the parameters of the study, then turns to inspection to develop sensitizing concepts about the study, finally developing theoretical concepts about society and its members (Hammersley, 1989).

The Chicago School

Blumer mentioned some works of the Chicago School and particularly *The Polish Peasant in Europe and America* (Thomas and Znaniecki, 1918–20) as exemplars of the naturalistic method. Indeed, many works of the Chicago School are considered the antecedents of SI, as they tended to rely on some facet of the naturalistic method. Both Mead and Blumer were at the University of Chicago in the 1920s and 1930s when the school had great influence on American sociology. Among many other important contributors to the naturalistic studies of the Chicagoans, besides W.I. Thomas, who was one of the

theoretical leaders (but left as early as 1918), Robert Park must be mentioned. He was a former journalist trained in philosophy and took some courses from the pragmatists, John Dewey and William James. From his previous profession Park brought an understanding of studying the real world 'out there,' thus, being the inspirator of many studies of naturalistic nature. It must be noted that the Chicago School has been criticized for saying very little about their methods in their writings (Hammersley, 1989) and for not really being a school of thought at all (Becker, 1999). Some of the most notable works from the Chicago naturalistic tradition are *The Ghetto* (Wirth, 1928), *The Delinquent Gang* (Thrasher, 1927), *The Gold Coast and the Slum* (Zorbaugh, 1929), *The Hobo: The Sociology of the Homeless Man* (Anderson, 1923). For a detailed study of the Chicago School see Faris (1967) and Bulmer (1984).

Other Methods Based on Mead

While Blumer's adaptation of Mead's theories is the methodological mainstay of SI, there are other methodologies based on SI, and these will be mentioned next. Analytic induction was first discussed by Znaniecki (1928). It was later used, with minor variations by Lindesmith (1937, 1968) (he was a graduate student of Blumer), Cressey (1950) (a student of Lindesmith), Becker (1963) (see Hammersley, 1989), and others. Analytic induction, according to Znaniecki, recognizes the fact that objects in the world are open to an infinite number of description and, thus, our account of them must be selective; this selectivity will be based on the interest at hand, which for sociologists is primarily social and cultural systems; commonly used sociological methods relying on preidentification (deductive) or superficial description (inductive) will not work, only analytic induction will accomplish the task. The researcher will select a small number of cases (10–12, usually) and study them in depth, continually defining and redefining the event and formulating and reformulating theoretical propositions until they will fit all cases. Negative cases must also be examined (this was Lindesmith's idea).

Another student of Blumer, Strauss, together with Glaser, developed another SI method, grounded theory (Glaser and Strauss, 1967). Closely related both to Blumer's methodology and to analytic induction, grounded theory placed more emphasis on the generation and development of theory. Relying on the inductive method, grounded theory is akin to Blumer's inspection, only much more elaborate. Rather than relying on a priori population, in analytic theorizing one continues to study new cases until the point of saturation, generating theoretical categories.

Not all SI methods followed the constructionist approaches outlined above. A notable exception came from the Iowa School of Sociology. Kuhn (1964) adopted a much more deterministic approach to Mead's discussion of the self and the nature of the 'me,' the various roles and images we have of ourselves. The methodology he adopted to discover the nature of the self was called the Twenty Statements Test (TST), a series of open-ended questions about the self. Kuhn felt that rather than use the oblique method of observing people one ought to ask them directly about the nature of their inner feelings and they would honestly disclose them to the researcher. The results of TST would be used, by Kuhn, to outline generic laws that would apply to human beings in different situations. Other positivistic oriented symbolic interactionists are Sheldon Stryker, described as a 'structural role theorist,' who influenced numerous students at the University of Indiana and Carl Couch, who was a stalwart of the discipline, with his 'Behavioral Sociology' at the University of Iowa (cf Reynolds, 1993).

In the 1960s and 1970s, a plethora of theoretical approaches, largely based on the naturalistic method, appeared. Some were based on basic Meadian tenets, such as dramaturgy (Goffman, 1959), and labeling (Becker, 1963). Others based their constructionist approach not only on the ideas of Mead but on those of the phenomenologists (Husserl, Schutz, Heidegger, Dilthey) and the existentialists (Merleau-Ponty, Sartre), and ordinary language philosophers (Wittgenstein). They are phenomenological sociology, existential sociology, ethnomethodology, and the sociology of emotions (see Douglas et al. (1980) for a survey of these sociologies and a list of references to them; also, see Adler et al. (1987), Moran (2002), and Grossman (2013)).

Postmodern-Informed Symbolic Interactionism

More recently, with the influence of postmodernism on the social sciences, the methodology of SI has undergone some dramatic changes (Marcus and Fischer, 1986; Dickens and Fontana, 1994). Again, the closeness of theory and methodology in SI affects methodological approaches to SI. Postmodernism (Lyotard, 1984) advocates a disenchantment with metatheories, claiming all we can possibly know about society is much smaller in scope, and it is relative due to its historical, temporal, regional nature, as well as other elements. Thus, society becomes fragmented and we should question and deconstruct all overarching metatheories and reduce the scope and intent of our studies to our immediate surroundings, to the details of everyday life.

These beliefs impact the naturalistic method of SI in a number of ways. First, we can no longer claim to be aiming at universal laws of human behavior as that would be a metatheory. Second, metatheories come under scrutiny and are deconstructed, i.e., their basic assumptions are rendered problematic and questioned. This leads to the questioning of the role of the researcher and author in terms of authority of selectively choosing data to record and report, thus biasing the study. Postmodern-informed interactionism attempts to remedy this authorial bias by the use of polyphony, by this meaning to allow the many voices of the respondents to speak for themselves. Additionally, researchers disclose as much information as possible about themselves – role, interest, possible bias, and more. This is only a partial solution to the authorial influence, which is ultimately, irremediable, as we cannot help but to perceive and report selectively.

Other methodological changes take aim at the relation between the researcher and the researched. Traditionally, interactionists have attempted to remain as neutral and invisible as possible in order not to influence the study. Postmodern-informed interactionists make their presence felt

in an attempt to establish a one-to-one partnership with the respondents. In so doing researchers are no longer aloof observers collecting data but become a part of the interaction and influence the research findings. Now data stems from a negotiated process between researcher and respondent (Gubrium and Holstein, 1997) (notice that this goal contradicts the previous goal of reducing authorial bias).

Another change involves the notion of 'value free' research. Some postmodern-informed interactionists wish to overthrow traditional sociology (Clough, 1998; Denzin, 1997, 1999a, 2001; Fontana and McGinnis, 2003) which they consider patriarchal, instead they envision a new researcher who is a "feminist, communitarian researcher … who builds collaborative, reciprocal, trusting, and friendly relations with those studied" (Denzin, 1997).

Current Trends

Postmodern-informed interactionists not only have made dramatic methodological changes from Blumerian interactionism but are experimenting with radically different reporting styles, which are closely intertwined with the new methodological ethos. Some of these styles include poetry and performances, as well as the writing of short stories about one's personal past (autoethnographies). While some of these reports are highly engaging (Richardson, 1997; Denzin, 1999b), they raise a question about standards – should these works be judged and evaluated by the standards of sociology or poetry and literature? Some interactionists have been highly critical of postmodern-informed interactionism (Seidman, 1991; Shalin, 1993; Best, 1995; Prus, 1996; Perrotta, 2004). As a result the field of interactionism is currently divided in many groups with different methodological approaches.

Adler and Adler (1999), in describing the varied groups of interactionists at the turn of the millenium, use the metaphor of 'the ethnographers' ball' and sit the factions at various tables. We will rely upon the Adlers' description in the following section. The first table sits the 'postmodern-informed' ethnographers, next to them is the 'autoethnography group,' a bit further down sit the 'interpretive discourse analysts' who attempt to integrate interactionism, ethnomethodology, and postmodernism. At another table the Adlers have the 'classic interactionists,' in the wake of the old Chicago School. Next to them sit the 'no mo pomo' (Adler and Adler, 1999), the Blumerian group critical of the new postmodern influence. Near by are the followers of Erving Goffman, the 'dramaturgists,' studying everyday life by using the metaphor of the theater. They are followed by the 'grounded theorists,' next to the 'conversational analysts' who are continuing the work of ethnomethodologists such as the late Harvey Sacks and others. Next, the Adlers have a table for those who practice 'the extended case study,' using ethnography to do applied research. Finally we see the 'visual interactionists' who capture symbolic interaction through the eye of the camera lens. As the Adlers themselves say, 'the list can go on' (Adler and Adler, 1999).

We would add to the Adlers' list three more tables, before we run out of room in the ballroom. One would be the 'phenomenological/existential' table placed near Jack Douglas and his former students at the San Diego campus of the University of California. Another table, right next to the postmodernists, would be the 'feminist interactionists' who are 'united in their criticisms of "Eurocentric masculinist approaches"' (Collins, quoted in Denzin, 1997). Finally, there would be a table of 'theoretical interactionists' who have written extensively in the area without actually engaging in ethnographic work (cf Lyman and Scott, 1989).

The methodology of Symbolic Interactionism has become the methodologies of symbolic interactionism, and can no longer be grouped solely under Blumer's guiding ideas, yet their diversity is exaggerated and exacerbated by rivalry among various subgroups (Fontana, 2005). By and large, while differing in some methodological points, the great majority of interactionists still wish to study the real world and the meaning that its members make of it and how they manage to maintain and achieve social order as a negotiated interactional accomplishment.

Symbolism in Anthropology

Janet Hoskins, University of Southern California, Los Angeles, CA, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

This article explores the importance of symbolism in anthropology, noting its role in the development of a 'school' of symbolic anthropology in the 1960s and 1970s, and the various positive and critical responses to this embrace of the ethnographic study of symbols. It concentrates on the works of Clifford Geertz, Victor Turner, David Schneider, Mary Douglas, and Sherry Ortner, since each of these thinkers has been seminal in developing this approach, although many others could also be included. I also explore the 'genealogical' criticism of the notions of religion and ritual as symbolic systems, particularly as articulated by Talal Asad.

This article explores the importance of symbolism in anthropology, noting its role in the development of a 'school' of symbolic anthropology in the 1960s and 1970s, and the various positive and critical responses to this embrace of the ethnographic study of symbols. It concentrates on the works of Clifford Geertz, Victor Turner, David Schneider, Mary Douglas, and Sherry Ortner, since each of these thinkers has been seminal in developing this approach, although many others could also be included. I will argue that Turner developed an approach to analysis of symbolism in ritual (defined most notably in his 1975 review article on *Symbolic Studies*), while Geertz explored symbols as 'vehicles of culture.' Schneider studied culture itself as a symbolic system, and Mary Douglas looked at symbols of purity and pollution as demarcating problems in social classification. Symbolic anthropology was more a number of shared concerns than a unified school, and some have argued that rather than being in constructive dialogue or conflicting with each other they managed only to 'talk past one another' (Ortner, 1984: p.131). But the tools developed to analyze and argue about symbols have remained useful in anthropological discussions into the twenty-first century.

In the final section of this article, I will explore what could be called the 'genealogical' criticism of the notions of religion and ritual as symbolic systems, particularly as articulated by Talal Asad. I will assess whether or not this criticism is based on a certain misunderstanding of the properties of symbolism as studied by anthropologists. I will also cite recent developments in relating the study of symbolism to theories of practice, especially Pierre Bourdieu's idea of a 'religious field of practice.' The study of symbolism in anthropology has shifted in new directions in the twenty-first century, orienting itself more toward ideas of discipline and control, and less toward the free play of multivocal symbols. But the topic has remained important and has shaped the history of the discipline.

Defining Symbolism

The Oxford English Dictionary defines a symbol as "a thing regarded by general consent as naturally typifying or representing or recalling something by possession of analogous qualities or by association in fact or thought" (Victor Turner, 1975: p.151). Applying this concept to anthropological analysis, the idea of 'general consent' would have to be limited to a particular cultural context, since meanings are in many senses culture bound. Symbolism has been central to definitions of culture ever since Kroeber and Kluckhohn wrote "culture considers of patterns explicit and implicit, of and for behavior acquired and transmitted by symbols, constituting the distinctive achievement of human groups" (Kroeber and Kluckhohn, 1952: p. 357). A quarter century later, Clifford Geertz echoed this definition with his own formulation of the culture concept as "an historically transmitted pattern of meanings embodied in symbols, a system of inherited conceptions expressed in symbolic form by means of which men communicate, perpetuate, and develop their knowledge about and attitudes toward life" (Geertz, 1973: p. 89).

Victor Turner has more than any other single anthropologist to define the forms and functions of symbols, and their relation to language. He argues that it is important to distinguish a symbol from a sign. A symbol can have multiple meanings and it signifies through a more complex process than a sign. The sensorily perceptible vehicle or 'outward form' is the signifier, and the meaning, sense, or designation is the signified. For signs, the signified is relatively straightforward, while for symbols it may be more complex and ambiguous. The linguistic sign signifies in ways that are arbitrary and conventional, while a symbol has a metaphoric or metonymic relationship to what it designates. Signs tend to univocality and are often deliberate constructs for precise communicative purposes, while symbols tend to be iconic, "where a sensory likeness relation is intended or interpreted" (Turner, 1975: p.152).

Turner defines the properties of symbols – multivocality, complexity of association, ambiguity, open-endedness, primacy of feeling, and a propensity to ramify into further semantic systems – as connected with their dynamic quality (Turner, 1975: p.155). Symbols can trigger social action and can give personal action form in the public arena. From Turner's perspective, "we master the world through signs, ourselves by symbols" (Turner, 1975: p.159). Turner developed a view of symbols as operators in the social process, which could produce social transformations,

particularly in the context of ritual. He applied this analysis to understanding Ndembu ritual, such as the temporary shrine to hunter-ancestors called the *chishing'a*. The *chishing'a* is a three or four pronged branched whose ends are sharpened to represent the 'sharpness' of huntsmanship. The bark is peeled to reveal its auspicious inner quality of whiteness associated in Ndembu thought with milk, and hence fertility and nurturance. Braided grass is tied under lowest prong to represent animals and ancestral shades who come up from the red grave to drink the blood offered to them by the hunters. These three aspects "form part of a complex verbal hermeneutic which encompasses the innumerable nonverbal symbols of Ndembu culture in webs of explicit significance" (1975: p.154).

Turner developed and elaborated this analysis of symbols not only to the Ndembu, but also to a wide range of other rituals, which he distinguished as 'performances' (Turner 1967, 1974, 1986, 1987). Theater was "one of the many inheritors of that great multifaceted system of preindustrial ritual that embraces ideas and images of cosmos and chaos, interdigitates clowns and their foolery with gods and their solemnity, and uses all the sensory codes, to produce symphonies in more than music" (1990: p.12). Ritual teases the senses as part of a process similar to what Turner had earlier called a 'social drama': There are four phases – a breach (of social rules), a crisis, redress, and either reintegration or recognition of schism (Turner, 1987: pp. 34–35). The stylized, scripted action of ritual defines a creative tension between "what should be performed" and "what actually happens," providing the potential for both continuity and change, since ritual is a way for members of a society to reflect on their own actions. As Turner has put it, "cultural performances are not simple reflectors or expressions of culture or even of changing culture but may themselves be active agencies of change, representing the eye by which culture sees itself" (Turner, 1986: 24). If, as Geertz argues, anthropological interpretation is defined as 'constructing a reading of what happens,' then ritual is one of the best places to isolate and analyze that 'reading' (Turner, 1975: p.148).

Religious Symbols and Cultural Systems

Turner's explicit acknowledge of Clifford Geertz in this final phrase signals the ways in which his approach is compatible with, but quite distinct from, the more cultural approach to symbolic interpretation, which Geertz has proposed. While Turner sees symbols as "instrumentalities of various forces – physical, moral, economic, political, and so on – operating in isolable, changing fields of social relationships" (Turner, 1975: p.145), Geertz sees them as part of a cultural system. Turner studied symbols as they are is performed in ritual, where he identified forms of dramas, fields, and metaphors in a series of detailed studies moving from the Ndembu out to a wide range of other societies. His famous notion of liminality (an 'in-between status') is developed through an analysis of the ritual process, in which the meaning of particular symbols is constituted through their effectiveness in producing transformations in rites of passage. He then extended the drama metaphor to studies in the 'anthropology of performance,' suggesting that that non-Western societies were cyclically enacting a dramatic script in successive performances of pilgrimages, rites of affliction, and calendrical festivals.

Geertz innovated by arguing that culture is not something private, hidden away inside individuals, but is embodied in public symbols. He defined his new paradigm for the study of religion by asserting that "sacred symbols function to synthesize a people's ethos – the tone, character, and quality of their life, its moral and aesthetic style and mood – and their world view – the picture they have of the way things in actuality are, their most comprehensive ideas of order" (Geertz, 1973: p. 89). The study of symbols was a way to understand the complex ways in which people communicate with each other and transmit their way of life to future generations. Geertz argued that the anthropologist should study 'the native's point of view,' as a sort of text that could read over the shoulders of native actors, and interpreted through an analysis that would make it intelligible to nonnatives. He defined anthropological interpretation, as 'constructing a reading of what happens,' and this cannot be done without having a sense of the whole to which it belongs. To divorce it from what happens "from what, in this time and place, specific people say, what they do, what is done to them, from the whole vast business of the world, is to divorce it from its applications and render it vacant" (Geertz, 1973: p.18).

The study of symbols for Geertz was, first and foremost, the study of religion: "Religious symbols formulate a basic congruence between a particular style of life and a specific (if often implicit) metaphysic, and in so doing sustain each with the borrowed authority of the other" (Geertz, 1973: p. 90). He also argued that symbols were part of a series of cultural patterns that provided both a 'sense of direction' and a 'power of self control,' adding "Man depends upon symbols and symbol systems with a dependence so great as to be decisive for his creatural viability" (Geertz, 1973: p. 99). Without them, we would be reduced to "a formless monster… a chaos of spasmodic impulses and vague emotions."

Religion as a cultural system creates 'an aura of utter actuality,' which all its symbolic activities are "devoted to producing, intensifying, and, so far as possible, rendering inviolable by the discordant revelations of secular experience" (1973: p.112). Ritual performances, like the elaborate Balinese dance drama opposing Rangda and Barong, which he analyzes, make "the model for and the model of aspects of religious belief mere transpositions of one another" (Geertz, 1973: p.118). Religious symbols offer a 'model of' the relations between the self and the world, and also a 'model for' how to act in this world, a set of distinctive 'mental dispositions' that motivate specific forms of action. Victor Turner argues that symbols can be used instrumentally, to trigger social action, while Geertz stresses the fact that they are first of all 'conceptions of a general order of existence' that provide both the map (the model of the world) and the specific instructions for the journey we should take across that territory.

Core Symbols and the Domain of Kinship

The attention that Clifford Geertz gave to religion as a locus for symbolism has been transferred to the domain of kinship in

the work of David Schneider. Schneider sought to study the internal logic of systems of symbols, and in particular the ways in which they might be organized around core symbols. In his methodology a symbolic system is studied by isolating its elements, specifying the internal relationships among those elements, and then characterizing the whole system in some way, stressing its core symbols, ideological principles, and the underlying structures of which is a surface expression. Culture is more radically cut off from social action in this approach, in order to explore the precise relationship between various terms. In an article examining kinship, nationality and religion in American culture, Schneider found that the three terms constituted a 'system' dependent

> on a distinction between the "pure" domain of kinship, defined in terms of the symbol of coitus and differentiated into two major aspects, relationship as natural substance and relationship as code for conduct, and a "conglomerate" domain of kinship, differentiated into "the family" on the one hand and an articulated system of person-defined statuses (genealogical) on the other. (Schneider, 1969: 123)

He found that each cultural domain contains a hierarchy of symbols devolving from a semantically bipolar core symbol: substance or natural order is opposed to, yet united with, code for conduct. The symbol of 'love' links conjugal and cognatic love and relates them to the central core symbol of coitus. The cultural notion of the "person" is "constructed out of symbols and definitions from various cultural domains … in relation to particular contexts and systems" (Schneider, 1969: p.17).

Researchers in this tradition should search for core symbols of 'diffuse, enduring solidarity' as centers of organization in cultural systems and subsystems of symbols. The dual aspects of relationship as natural substance and relationship as code for conduct are defined and structured in almost identical terms in the domains of nationality and religion as well as kinship.

Symbols, Classification, and Taboo

Anthropological studies of symbolism address what Geertz called 'the problem of meaning' in a number of different ways. The British anthropologist Mary Douglas stresses the power of classification to order the world and make it conceptually manageable. There have been a number of other theories of taboo. Relational theories, like that of Levi-Strauss in his work on *Totemism*, project the relations of society upon the relations in nature. Moral theories argue that taboos create dangers that reinforce the moral code. This was the approach taken by Freud in his analysis of Moses and monotheism. Her own approach is a 'housekeeping model,' which views pollution as an aid to 'imposing system' on 'an inherently untidy experience,' equating anything that does not fit into tidy conceptual categories as dirt, since "dirt is matter out of place." As she argued in 2000 (p. 2288): "Taboos stop the cosmos from disintegrating. It is a process of learning by not doing. The strange connections taboos make between actions and consequences are not due to faulty logic but to a formidable intellectual effort to link nature and morality into a single scheme."

In 1966, Douglas published her most celebrated work, *Purity and Danger: an Analysis of Concepts of Pollution and Taboo*. This book is best remembered for its stylish demonstration of the ways in which all schemes of classification produce anomalies: whether the pangolin for the Lele, or the God incarnate of Catholic theology. Some of this classificatory 'matter out of place' – from humble house dust in her Highgate house to the abominations of Leviticus for the Hebrews – was polluting, but other breaches of routine classification had the capacity to renew the world symbolically.

In *Natural Symbols* (1970), Douglas began to answer the question that arose from this: what kinds of society are best able to support the complex symbolism that makes the best society possible? The book took exception to some 1960s cultural trends – notably the liturgical reforms of the Second Vatican Council and student revolts – and presented the first of many attempts to correlate features of institutional organization with patterns of belief and morality. Her conclusion – that differentiated, hierarchical and bounded institutions provided the most conducive environments for complex thinking and symbolism – remained the same, whatever changes her theories underwent.

Mary Douglas affirmed that all human beings have a profound need for a theory of a general order of existence, and religious symbols fulfill that need. In *Purity and Danger* she wrote that it was almost inconceivable for a person in a traditional society to be without religion: "The person without religion would be the person content to do without explanations of certain kinds, or content to behave in society without a single unifying principle violating the social order" (1975, p. 76). The deep dread of disorder that she assumed was common to all human beings was also evoked in Geertz's discussion of why religions come into being: "there are at least three points where chaos – a tumult of events, which lack not just interpretations but *interpretatability* – threatens to break in upon man: at the limits of his analytic capabilities, at the limits of his powers of endurance, and at the limits of his moral insight" (1973: p.100). Religious symbols must work to meet these perceived threats of intellectual, physical, and moral dissolution.

While the problem of meaning affirmed "the inescapability of ignorance, pain, and injustice on the human plane," it also had to simultaneously deny that "these irrationalities are characteristics of the world as whole. And it is in terms of religious symbolism a symbolism relating to man's sphere of existence to a wider sphere within which it is conceived to rest, that both the affirmation and the denial are made" (Geertz, 1973: p.108). Faced with resolving this problem of meaning, Geertz asserts that "He who would know must first believe" (1973: p.110), so a commitment to a religious perspective begins as a state of mind rather than a constituting activity in the world.

The Genealogical Critique of Religion as a Symbolic System

Perhaps the most influential criticism of the paradigm of symbolic anthropology has come from Talal Asad's post-structuralist perspective. He begins by saying "the theoretical

search for an essence of religion invites us to separate it conceptually from the domain of power" (1993: p. 29). Using the Foucauldian notion of the genealogy, he traces a history of notions of religion that emphasizes power, discipline, and coercion more than symbolic expressiveness. Asad argues that Geertz's 'interior' view of religion (focusing on subjective states of belief or faith) and ritual is both Eurocentric and presentist: it has emerged from a modern conception of religion that is not applicable to many other societies, or even to the earlier history of Christianity. But Asad's attack on Geertz' approach as secretly 'Protestant,' since it focuses on the believing individual as the prime locus of religion, does not take account of the fact that one reason to formulate a 'symbolic' definition of religion was to avoid the more conventional definitions (widely used in religious studies), which require a textual tradition, an institutionalized set of religious specialists, and physical structures – 'books, clergy, and temples.'

Geertz was writing as an anthropologist who was determined to grant the term 'religion' to less institutionalized practices like shamanism, ancestor worship, spirit possession séances, and forms of 'popular religion' usually excluded from earlier definitions of religion as incoherent and premodern forms not yet worthy of the term. But placing his emphasis on shared symbols, he does not have to require written doctrine or a formalized set of scriptures, but can include religious activity that is more improvisational, context dependent, dynamic, and emerging.

Both Geertz and Asad have tried to escape the limits of the modern Christian perspective, but they have done so in different ways. The first significant difference lies in ideas of the concept of the symbol. Geertz says that "religion is a system of symbols" and he defines a symbol as any object, act, event, quality, or relation that serves as a vehicle for a conception – the conception is the symbol's 'meaning.' Asad, in contrast, argues that a symbol is "a set of relationships between objects and events uniquely brought together as complexes or as concepts, having at once an intellectual, instrumental, and emotional significance"(1993: p. 31).

This difference of opinion may seem technical and of little consequence, but it has great importance for the kinds of research questions that can be investigated. While Geertz sees a system of symbols in place, which has to be decoded by the researcher, Asad is interested in the question of how (under what conditions) symbols come to be constructed and accepted as natural and authoritative, while others are opposed. Asad argues that the most important object of anthropological inquiry is "the conditions (discursive and nondiscursive) that explain how symbols come to be constructed, and how some of them are established as natural or authoritative as opposed to others" (Asad, 1993: p. 31).

Geertz's argument that religious symbols act as models of and models for reality follows in the tradition of Durkheim and Talcott Parsons, but Asad rejects this implied isomorphism. He asks instead how religious power has created an idea of religious truth through a series of embodied practices that make religion more a form of social activity than a system of beliefs. Looking at the early history of the Christian church, Asad argues that Augustine used discipline to push his disciples to experience Christian truth: "It was not mind that moved spontaneously to religious truth, but power that created the conditions for experiencing that truth. Particular discourses and practices were to be systematically excluded, forbidden, denounced – made as much as possibly unthinkable; others were to be included, allowed, praised, and drawn into the narrative of sacred truth" (Asad, 1993: p.35).

Geertz and Asad also differ on the role of ritual. While Geertz sees ritual as a signifying activity distinct from instrumental behavior, Asad sees it as an "apt performance of what is prescribed, something that depends on intellectual and practical disciplines but does not itself require decoding" (Asad, 1993: p. 62). It is coded in a regulatory way rather than in a semantic way. Instead of opposing symbolic to instrumental behaviors, he looks at the varied disciplinary programs through which a subject with virtuous desires was created. Asad says the West's emphasis on possessive individualism is in contrast with Islam's communitarian emphasis on virtue making as a collective responsibility. Current ideas of religious privacy and individual autonomy are incompatible with Muslim ideas of communitarianism and discipline.

Asad concludes that no universal definition of religion can be established, since all such definitions are the historical product of culturally specific discursive practices. "It is not mere symbols that implant true Christian dispositions, but power," and this power is deployed in an "entire range of available disciplinary activities… through which the possibilities of attaining the truth are marked out" (p. 50). He also accuses Geertz of conflating cognitive and communicative issues.

The modern Christian perspective marginalizes "the authorizing process by which 'religion' is created" (p. 37) and overlooks the fact that one can be religious "without being able to articulate that knowledge" (p. 36). Geertz' interpretive theory is said to deny the material, coercive side of the state, and material aspects of religion, which have shaped embodied practices and the experience of religion.

Geertz vs Asad and Bourdieu on Public Symbols and Private Discipline

The role of belief vs practice is a key point of disagreement. Asad accuses Geertz of tying his notion of religion to a cognitive notion of belief, as "a set of propositions to which believers gave assent," which allows religion to be separated off into a private domain. "Geertz's treatment of religious belief…is a modern, privatized Christian one because and to the extent that it emphasizes the priority of belief as a state of mind rather than as a constituting activity in the world" (Asad, 1993: p. 47). Asad argues that this shows a "Christian bias": "It is preeminently the Christian church that has occupied itself with identifying, cultivating and testing belief as a verbalizable inner condition of true religion" (p. 48).

Geertz distinguishes religious from nonreligious practices by claiming that a religious practice is one which affirms (something) about the fundamental nature of reality: "What any particular religion affirms about the fundamental nature of reality may be obscure, shallow. Or all too often perverse, but it must, if it does not consist of the mere collection of received practices and conventional sentiments we usually refer to as moralism, affirm something" (Geertz, 1973: pp. 98–99,

Asad, 1993: p. 43). Asad argues that this definition tends to exclude the "unevangelized" who come to be seen "typically either as those who have practices but affirm nothing, in which meaning can be attributed to their practices (thus making them vulnerable), or as those who do affirm something (probably 'obscure, shallow, or perverse'), an affirmation that can therefore be dismissed" (Asad 43).

The claim may not hold water. 'Belief' itself is not even mentioned in Geertz' definition, although his idea of a 'model for' and conceptions 'clothed in an aura of factuality' might be taken as leading to a certain metaphysics. His examples of religious symbols ("elaborate initiation rites, dramatic shamanistic exhibitions, cruel human sacrifice rites, obsessive curing ceremonies, large communal feasts") are all focused on the religious practices of 'unevangelized' non-Western groups (Australian aborigines, the Maori, the Eskimo, the Navaho, Polynesian groups). Rather than accepting a modernist strategy that religion occupies the space of noncognitive feeling or experience, Geertz explicitly insists that religions are interested in teaching a world view.

Geertz also argues strenuously that symbols are public. He says culture is "not anybody's knowledge or belief about anything" (1973: p. 12). It is instead embodied in public acts: "Culture is public because meaning is. … Culture consists of social established structures of meaning in terms of which people do such things as sign conspiracies and join them or perceive insults and answer them" (Geertz, 1973: pp.12–13). His famous essay on *Thick Description* is primarily an attack on 'the cognitivist fallacy' that culture consists of mental phenomena, which can be analyzed by formal methods. Here, Asad seems to have fundamentally misunderstood Geertz' position. After all, it is Geertz – not Asad – who argues that "cultural acts, the construction, apprehension and utilization of symbolic forms, are social events like any other" (Geertz, 1973: p. 91).

In a later essay (which could be interpreted as a veiled rejoinder to Asad), Geertz argues that religion is "the symbolic contrivances by means of which individuals imagined themselves as persons, as actors, sufferers, knowers, judges, as, to introduce the exposing phrase, participants in a form of life" (Geertz, 2000: p.15). The crux of Asad's argument is that one cannot assume a symbolic system separate from practices. Geertz' famous position that culture can be studied as an 'ensemble of texts' implied that these cultural elements are disembodied, abstracted from action. Drawing on the hermeneutic philosophy of Paul Ricoeur and a Weberian vocabulary of meaning, pattern and interaction, Geertz proposes that we can study the systems of meaning on their own. To his critics, this seems to detach meaning from practice, leading Bourdieu (1977, p. 96) to criticize the hermeneutic stance as 'objectivism.'

Alternatives to Symbolism: A Religious Field of Practice

What alternative approaches to the study of religion would allow us to study symbols in the context of relations of power? Pierre Bourdieu has developed a concept of the 'religious field of practice' (Bourdieu, 1971). A religious field comes into being when a class of religious specialists emerge and try to centralize, systematize, and control a body of knowledge. In doing so, they assert their religious authority and create a field of power in which others are disqualified as laypeople or dismissed as practicing 'superstition,' 'magic,' or some lower form of popular religion. The 'search for meaning' that Geertz describes as motivating the elaboration of symbolic systems is part of this field of practice, but Asad would say that it would be naive to separate this search from the historical dynamics of relations of power.

Asad follows his critique of the definition of religion with another chapter on the concept of ritual. He insists that the idea that ritual is essentially a symbolic, signifying behavior is entirely modern. In his view, anthropologists and historians are performing a theological task when they establish a master meaning of representations by declaring that the (often conflicting) explanations offered by the performers of rituals are inadequate. It is not the role of the scholar to interpret these traditions, he says, but to trace their histories and the ways in which they have been discursively constructed.

Asad's genealogy of ritual concludes with this observation: "Symbols… call for interpretation, and even as interpretative criteria are extended, so interpretations can be multiplied. Disciplinary practices, on the other hand, cannot be varied so easily, because learning to develop moral capabilities is not the same thing as learning to invent representations" (1993: p. 79). His phrasing seems to imply that interpretive studies of symbolism may multiply throughout a hall of mirrors without leading us on to greater knowledge, while the more grounded study of disciplinary practices and the ways in which they come to establish an authoritative discourse rests on somewhat firmer ground.

The question of religion and ritual cannot, in Asad's eyes, be raised without also considering the contrasting process of secularization. Asad's position is that the boundary between secular and religious has been constantly redrawn in Christianity, and anthropologists need to be aware of the fact that their discipline is defined by its conceptual site in the modern world: "It is not just that anthropology is a modern creation born out of Europe's encounter with non-Europeans. It is that the major ideas it used to grasp its subjects (nonmodern, local, traditional) are often dependent on the contrastive sense of the modern" (Asad, 1993: p.19).

This then brings up the question of how one could develop a critical examination of the modernity of symbolic systems within the discipline of anthropology. Asad himself considers David Schneider's 1984, *Critique of the Study of Kinship* an 'outstanding example' of such a study by an anthropologist (Asad, 1993: p.19). Presumably, this is because it calls into question the naturalized concepts of family, sexuality and marriage within American culture, and shows how their symbolic construction has a specific history. The first reader to try to programmatically describe the project of 'symbolic anthropology' was in fact coedited by David Schneider and J.L. Dolgin (Dolgin and Schneider, 1977). Schneider's approach has been very influential in inspiring a new generation of anthropologists who have fused the insights of symbolic anthropology with an awareness of practices and their relation to systems of power, celebrated in Ortner's 1984 review of emerging 'theories of practice.'

Abstract

Self-reported health complaints result from a complex integration of interoceptive (bottom-up) information emerging from peripheral physiological activity with (top-down) perceptual-cognitive and affective processes. Interoceptive signals have to be sensed, perceived, attended to, appreciated and interpreted, put into language and expressed, mostly in a social context. In this article, we will discuss the role of perceptual and attentional processes, anticipation, symptom schemata and illness beliefs, emotion and personality, and memory processes. Their role may importantly influence the relationship between indicators of peripheral physiological activity and self-reported health complaints.

Interoception and Symptom Perception

Although all self-reported health complaints are the result of processes in the brain, a general assumption is that they accurately reflect dysfunctional processes in the peripheral body. The afferent or sensory processes transmitting information from the body to the brain can be called interoception. However, although interoception and symptom perception are related processes, they are not the same.

Interoception

Interoception is poorly defined and several definitions are used. Some equalize it rather narrowly with visceroception (Dworkin, 2000), whereas others (Craig, 2004) also include proprioception and somatoception (the perception of stimuli interacting with the body surface). Still others conceive of interoception more broadly as a meta-representation of the body's state allowing the brain to distinguish the inner from the outer world (Mosely et al., 2012).

Recent neurobiological research has shown that sensations from within the body, such as hunger, thirst, stomach cramps, fullness, rectal urgency, temperature, itch, muscle ache, dyspnea, pain, etc., are processed in a shared evolutionarily ancient neural pathway that serves to maintain the integrity of the body or, in other words, homeostasis. Several comprehensive reviews (Craig, 2002, 2004) suggest that interoceptive pathways include a sensory branch carrying signals to the lamina I and the medullary nucleus of the solitary tract, which are (in humans) integrated in the parabrachial nucleus to travel via parallel ascending pathways to the ventromedial thalamic nuclei further to the mid/posterior insular cortex, in which a modality-selective representation is produced underlying distinctive sensations.

Via ascending afferent pathways providing a direct thalamocortical connection to the anterior cingulate cortex (ACC), interoceptive sensations also become endowed with affective-motivational value (e.g., unpleasantness). The interoceptive image is further rerepresented in the right anterior insula, which is also involved in subjective awareness of feelings and emotions. This process of rerepresenting progresses from the posterior to the anterior parts implies a successively increasing "integration of homeostatic, environmental, hedonic, motivational, social and cognitive activity to produce a 'global emotional moment,' which represents the sentient self" (Craig, 2009: p. 67). This allows for a bidirectional influence of emotion and interoception (Critchley et al., 2001; Zaki et al., 2012). For example, accurate cardiac perception is associated with more intense emotional experience (Herbert et al., 2010), and state negative affect enhances the activation of the right anterior insula and the dorsal ACC (Mayer et al., 2006). The ACC has further strong interconnections with cortical prefrontal (PFC) regions as well as strong descending projections, particularly, to the periaquaductal gray (PAG) and the brain stem, allowing for top-down facilitatory and inhibitory modulation on interoception from higher cortical regions (Mayer et al., 2006). Top-down modulatory processes may go as far as to influence neural activity at the level of the spinal cord (Eippert et al., 2009).

This short neurobiological account shows that there is room for multiple top-down processes to modulate the experience of sensations from the body and different functional aspects of interoception (Garfinkel and Critchley, 2012) have been distinguished. For example, on both neurobiological and functional grounds, a distinction can be made between interoceptive accuracy, which refers to the ability to accurately perceive one's own internal activity, and interoceptive or body awareness, which refers to the state of being cognizant, mindful of one's own internal state (Khalsa et al., 2008, 2009; Ceunen et al., 2013). Interestingly, heightened body awareness can be both adaptive and maladaptive for perceived health (Mehling et al., 2009), whereas evidence shows that elevated symptom reporting may be related to reduced interoceptive accuracy (see further).

Symptom Perception

Symptom perception can be defined as the process of becoming aware of bodily dysfunction. Although symptom perception can theoretically be distinguished from symptom reporting or self-reported health complaints, these concepts are

often used interchangeably. Perceived internal sensations turn into health complaints when they become endowed with negative affective value and become part of a meaning network associated with potential threat to the integrity of the body. In this respect, bodily symptoms can be conceived of as 'homeostatic emotions' (Craig, 2003): they involve a sensory component serving the experience of intensity, location, and other qualities of internal sensations, and an affective-motivational component providing the drive for behavioral action to promote survival. Accurate and aware perception of bodily dysfunction may, therefore, be considered the behavioral layer in a hierarchical defense system to protect the integrity of the body: the behavioral action system is engaged when automatic, more local, automatic and reflexive regulatory systems within the body fail. For example, the experience of breathlessness interrupts ongoing activities, rearranges processing priorities and is associated with a compelling drive to gasp, opening the window, and/or fleeing from closed places to compensate for inaccurate automatic regulation of blood gases.

The process of becoming aware of bodily dysfunction typically includes putting perceived sensations into words, which are part of, or constitute, meaning networks. The semantics of symptom words are particularly relevant for symptom assessments. Most questionnaires use a variety of symptom words, which are clustered according to physiological systems, such as cardiorespiratory and gastrointestinal symptoms. However, other relevant underlying aspects in symptom reporting tend to be overlooked and more sophisticated analyses of dimensions underlying somatic symptom reporting are needed (see Jasper et al., 2012). Indeed, items used in assessment instruments may differ according to other aspects as well. Some inquire about a mere sensory aspect (e.g., fast/deep breathing), while other items also probe an implicit appraisal of its unpleasantness (i.e., 'breathlessness'). Both aspects can reliably be distinguished (von Leupoldt et al., 2006; Wan et al., 2009), but individuals differ in how they intuitively integrate both components (Petersen et al., 2011). Several other relevant dimensions can be distinguished, such as the extent to which a symptom word refers to a specific location in the body or to a systemic state (compare 'tooth ache' with 'tiredness') and the probability of a symptom to be life threatening (compare 'running nose' with 'blood in stools'), etc. Few studies have looked at the role of psychological processes to select or endorse particular wordings to describe one's own internal state (but see Van Diest et al., 2005).

Just like any other type of information entering conscious awareness, information from within the body is sensitive to modulation by functional psychological processes. The seminal work of Pennebaker (1982) on the psychology of physical symptoms introduced most processes elaborated on in later, more detailed models. These processes include attention, expectation, memory, attributions and illness beliefs, emotions and personality (Rief and Broadbent, 2007). In the following, we will discuss a number of relevant psychological processes and how they influence symptom perception. Although several processes are discussed separately, it should be clear that they are mutually interacting to construct a unified somatic experience for the 'sentient self.'

Psychological Modulation of Symptom Perception

Perception and Attention

Critical dimensions for symptom perception are intensity and location of interoceptive stimulation. A general rule seems to be that psychological modulation of bodily symptom perception is less pronounced when the interoceptive stimulation is intense and unambiguous in time (on/off) and location. In these conditions, a rather direct relationship between the interoceptive stimulation and symptom reports exists (Stegen et al., 1998; Put et al., 2004; Martin et al., 2003). Most often, however, interoceptive information is low- to mildly intense and has no clear spatial and/or temporal boundaries, particularly, when the physiological dysfunction is systemic. In such conditions, attention seems to play an important role. Attention, a process involving the allocation of processing resources to stimuli, typically amplifies psychophysiological and behavioral responses to attended stimuli, whereas distraction from these stimuli reduces such responses (Bushnell et al., 1999). Attentional focus can result from local, bottom-up stimulus characteristics (e.g., novelty) or from top-down processes, such as anticipation.

Two important questions emerge as regards attention and symptom perception: is attention 'directed inward' influencing the number and intensity of perceived bodily symptoms, and is it influencing the accuracy of symptom perception (defined as the within-subject correspondence between physiological and self-reported changes)? As to the first question, direct manipulations of attention to the body and studies assessing body awareness generally show that attention focused on the body enhances the sensitivity to interoceptive stimulation and increases symptom reports. This has been documented by studies on tactile stimulation (Mirams et al., 2012), respiration (Stegen et al., 2001), pain (Villemure and Bushnell, 2009), itch (Van Laarhoven et al., 2010), dyspnea (von Leupoldt et al., 2007), and general symptom reporting (Verkuil et al., 2007). Interestingly, not just symptom reports but also objective cough frequency is enhanced by focusing attention on internal sensations (Van den Bergh et al., 2012). Consistent with such findings, it has been shown that performance on concurrent cognitive tasks is disrupted as a result of attentional resources being consumed by noticing interoceptive stimulation (Stegen et al., 2001; Eccleston and Crombez, 1999). Conversely, distraction from bodily sensations generally reduces the perceived intensity of interoceptive stimulation and symptom reports (Pennebaker and Lightner, 1980; Coen et al., 2008; Accarino et al., 1997). The role of attention for symptom reports has been captured in the 'cue-competition hypothesis' (Pennebaker, 1982), assuming that the amount of interoceptive information reaching awareness is a function of the ratio between the amount of interoceptive and exteroceptive information. Findings that persons living in boring environments tend to report more symptoms than persons living in rich and stimulating environments are in line with this hypothesis.

As to the second question, evidence suggests that an interoceptive attentional focus is not necessarily associated with better interoceptive accuracy, but rather with a tendency to overestimate the intensity of somatic sensations. In a study applying low-intensity tactile stimuli, it was shown that a more

liberal response criterion was used when attention was directed inward, leading to more false positives (Mirams et al., 2012). Some groups, such as persons with high-trait negative affectivity (NA) who tend to focus attention inward during a physiological challenge (Stegen et al., 2001), report more symptoms, which are less closely related to the induced physiological changes (Van den Bergh et al., 2004; Bogaerts et al., 2005). Also persons with somatoform disorders, who are typically preoccupied with sensations in the body, reported more symptoms as shown by their interoceptive accuracy to be lower (Schaefer et al., 2012) compared to healthy controls.

Yet an unresolved question is whether the emotional significance of an interoceptive sensation interacts with its sensory processing. Substantial evidence shows that the amygdala serves as a 'neurological hub' swiftly assessing the emotional value of exteroceptive sensory events and subsequently enhancing perceptual processing in early sensory pathways through connections with sensory areas in more distant cortical regions (Pourtois et al., 2013). Claims are made that similar attentional prioritization and subsequent enhancement of processing occurs for potentially noxious stimuli in the 'peripersonal space' (the body and the space surrounding it) (Legrain et al., 2011), but it is not known whether similar mechanisms operate when processing stimuli originating from within the body.

Anticipation, Symptom Schemata and Illness Beliefs

A wealth of evidence on placebo and nocebo documents the dramatic effects of expectations on symptom perception and reporting. Anticipation can be induced either by classical conditioning, verbal instructions, and all kinds of contextual factors. It should be noted that conditioned placebo and nocebo effects do not necessarily depend on conscious expectation (Benedetti, 2013). Effects can impact the intensity, but also determine the sheer presence/absence of symptoms. Particularly, pain analgesia has been thoroughly investigated and a so-called descending pain modulatory network has been described, involving prefrontal (Dorsolateral PFC), limbic (ACC, amygdala), midbrain (PAG), and even spinal cord areas. Knowledge about the mechanisms involved in placebo and nocebo phenomena related to other sensations than pain is more sketchy, but sufficient to document the pervasive effects of anticipation on neurotransmitter function, including the endogenous opioid system, and on autonomic, endocrine, immune, and motor functions (Finniss et al., 2010; Enck et al., 2013). Such findings show that symptom perception involves a bidirectional process without a marked boundary between central and peripheral processes. Bottom-up processes relay information of peripheral physiological activity to the brain, but cognitive processes (critically requiring the involvement of prefrontal areas, such as the dorsolateral PFC) in turn substantially influence activity in other central neurobiological and in peripheral physiological systems. These specific systems may differ according to the type of placebo or nocebo response (Benedetti, 2013).

Symptom schemata typically result from repeated symptom episodes. It is assumed that the person's history with symptoms episodes is recorded in memory and represented in the form of schemata, which capture the commonalities among different symptom episodes. Because some people had more episodes than others, while repeated symptom episodes can result from the same or from different health problems, symptom schemata can differ in complexity and coherence (Petersen et al., 2011). Symptom schemata act like perceptual categories: When activated or primed, a readiness to perceive an interoceptive stimulus configuration in a particular way is facilitated. The benefit is that less information has to be checked and controlled for a symptom experience to emerge, speeding up the perceptual process, but the ease of perception may come at a cost showing up as an elevated probability toward biased perception. For example, the slightest change in respiratory effort may be noticed by an 'experienced' asthma patient, whereas the same change may not reach awareness of the not-yet diagnosed or novice asthma patient. Conversely, an asthma patient who is concerned about potential attacks may easily misperceive respiratory distress caused by stress-induced hyperventilation as signs of an impending attack. Even simple magnitude judgments of respiratory resistance and related affective and behavioral responses are affected by primed perceptual categories of high or low respiratory effort (Petersen et al., 2014).

Just like the perception of a chair is automatic, categorical, meaningful and constructive, so is symptom perception the result of similar basic and automatic perceptual-cognitive processes. These involve a process of mapping sensory evidence on perceptual hypotheses, representing some kind of implicit reasoning. This was captured by Brown's model when postulating a primary attentional system (Brown, 2004). In line with research on perception, it hypothesizes that sensory stimuli are activating perceptual hypotheses in a feed-forward process and that actual information is gradually mapped onto them, giving rise to awareness of only this perceptual hypothesis that obtains the highest level of evidence (e.g., becomes a percept). The higher the activation state of symptom schemata, the less evidence from peripheral stimulation is needed in order to result in percepts. Ultimately, percepts may emerge without peripheral input at all, such as in placebo or nocebo symptoms, which then can be characterized as 'somatovisceral illusions.' For example, when participants were given an air mixture to breathe for a number of times, consisting of a harmless odor and CO_2-enriched air causing bodily symptoms, elevated symptom reports emerged upon subsequently breathing a mixture of the harmless odor only. These nocebo symptoms were similar to the symptoms originally induced by CO_2-inhalation and apparently resulted from automatically activated symptom schemata biasing the subject's perception of his/her somatic state (Van den Bergh et al., 1997, 1998).

However, once symptoms are felt, people may contemplate upon them, link them to an illness label, infer potential causes, anticipate about their consequences, and worry and ruminate about them. In other words, they develop an illness theory, elaborate on it and behave accordingly. The interpretation of palpitations as a symptom of an acute heart condition will prompt completely different behaviors compared to believing that they result from drinking too much coffee. This secondary process may, however, prime perceptual categories and modify the amount of evidence needed for a somatic percept to emerge, with potentially beneficial or disadvantageous

outcomes. In extreme cases, chronic activation of perceptual hypotheses, possibly as a result of catastrophizing, worrying and ruminating, may contribute to somatovisceral illusions, underlying medically unexplained symptoms (MUS) (see further).

Emotion and Personality

A robust association between symptom reporting and trait NA is consistently found ($r = 0.40$ to 0.50). Trait NA is a broad and stable disposition to appraise situations as more threatening and to experience negative mood states and emotions (Watson and Clark, 1984). It can be described as an overreactive evaluative system combined with poor or deficient emotion regulation when processing emotional stimuli (Yiend, 2010). It appears to have a genetic basis, is associated with distinct brain circuit function and neurotransmitter activity (Hariri, 2009) and is considered a vulnerability factor for emotional disorders, such as anxiety and depression (Lonigan and Vasey, 2009).

The association with symptom reporting reflects the effect of NA upon symptom reporting rather than vice versa (Watson and Pennebaker, 1989). The association appears in non-consulting healthy persons (Van Diest et al., 2005), in primary care patients where MUS cooccur with elevated anxiety and depression levels (Kroenke, 2003), and in patients with functional syndromes showing elevated psychiatric comorbidity (Wessely et al., 1999). In addition, also in known diseases a substantial correlation between symptom reports and NA exists (Janssens et al., 2009), reflecting a tendency to overreport symptoms in high NA persons. Closer inspection suggests that the depressive component of NA is mainly associated with 'overreporting' of past symptoms, whereas the anxiety component is more related to excessive reporting of concurrent symptoms (Suls and Howren, 2012). Also, not all symptoms are associated with NA. Van Diest et al. (2005) investigated the relationship between 73 individual symptoms and NA in a large healthy sample and found a wide variability (r's 0–0.45), which could be explained by two factors, namely severity (whether a symptom was potentially life-threatening) and 'somatic versus psychological' (whether a symptom was vague and possibly associated with anxiety; e.g., compare 'stuffed nose' vs 'loosing contact with reality').

Interestingly, also state negative affect impacts symptom perception. When presenting unpleasant emotional cues during experimentally induced bodily sensations, like pain (de Wied and Verbaten, 2001; Meagher et al., 2001), dyspnea (Von Leupoldt et al., 2006), or esophageal stimulation (Philips et al., 2003), symptom reports are more elevated. Even very short presentations of unpleasant pictures can result in increased symptom reports, particularly, in persons with high-habitual symptom levels, and/or high negative affect (Bogaerts et al., 2005, 2008; 2010; Constantinou et al., 2013) and in patients with functional syndromes (Montoya et al., 2005).

Several hypotheses have been advanced to understand this relationship. One idea is that persons with NA and/or during negative affective states have higher levels of sympathetic activity, which would translate into elevated self-reported symptoms. However, several extensive laboratory and ambulatory studies have not been able to document significant differences in a wide variety of peripheral physiological stress or arousal indicators (Houtveen and van Doornen, 2007). Recent studies are inspired by the hypothesis that inflammatory load and immune-related mechanisms are involved and that the relationship between negative emotional states and elevated symptom reports results from stress-related sensitization of the brain-immune communication, but only scanty evidence exists so far in support of this idea (Lacourt et al., 2013, 2012).

Another idea emphasizes attentional mechanisms leading to lower perceptual thresholds for (normal) physiological arousal responses to enter awareness. A set of studies by Gendolla et al. (2005) suggested that self-focused attention in conjunction with negative mood is critical for elevated symptom reports to occur. The interpretation advanced for these findings is that attentional focus on one's own negative mood would activate symptom schemata biasing reports of one's somatic state. However, self-focused attention seems not critical: simply viewing pictures with negative valence also elicits elevated symptom reports in high NA persons (Bogaerts et al., 2010; Constantinou et al., 2013). Apparently, simply processing negative cues, either in the internal or the external world, triggers symptom schemata and makes people prone to biased symptom perception, particularly, in persons with high NA.

Memory

Symptom assessments during diagnosis and treatment evaluations importantly rely on memory information. "How did you feel?" is an often heard question in the doctor's office, but also screening and assessment instruments measuring symptoms in general or related to a particular disease typically use retrospective frequency estimates over a long, often unspecified time window. Questionnaires typically require the respondent to rate a set of symptoms along intuitive standards such as seldom, frequent, almost daily, etc. (Zijlema et al., 2013). In such conditions, symptom reports are mainly based on memory of somatic episodes. The importance of symptom assessment being memory based is often overlooked despite the fact that memory is not just storing an experience, but is actively reconstructing it. Only when actual symptoms are assessed (how do you feel now?), either during doctor visits or with (often disease-specific) questionnaires, momentary information is collected. Evidence suggests that even then, there is no clear one-to-one relationship between physiological responses and self-reported complaints (Walentynowicz et al., 2013). Increasingly, time- or event-related multiple momentary assessment is used to assess symptoms in daily life (Shiffman et al., 2008), allowing for interesting comparisons between concurrent and retrospective ratings spanning the same symptom episodes and assessment period.

The majority of findings suggest a consistent overestimation of past symptoms as measured with global retrospective symptom ratings (Stone et al., 2004; Giske et al., 2010; Linton and Melin, 1982; Broderick et al., 2008). However, several factors relating to characteristics of the symptom episodes, the duration of the recall period, the context during recall and individual differences seem to moderate this overestimation, often resulting in a complex picture. For example, retrospective overestimation of pain was greater with lower initial pain,

while high initial pain was associated with underestimation (Feine et al., 1998). Also the variability of symptoms is an important variable (Stone et al., 2005): greater momentary variability was associated with greater discrepancy between momentary and retrospective ratings and higher retrospective ratings overall. Overestimation typically also increases with longer recall periods (Broderick et al., 2008), although in a study recording physical symptoms in daily life in students, a gradual increase in overestimation of experienced symptoms with longer time frames was observed only among high, but not low habitual symptom reporters (Houtveen and Oei, 2007). Furthermore, actual state during recall plays a role: lower current pain intensity at the moment of recall was associated with underestimation of recalled pain, whereas higher current pain was associated with overestimation (Smith and Safer, 1993; Lefebvre and Keefe, 2002; Gendreau et al., 2003).

A well-investigated memory bias is the so-called peak-end effect in retrospective evaluations. This refers to the observation that not all constituent elements of an experience are equally important when representing it in memory: the intensity of an experience at both the peak and the end receive relatively more weight as these episodes convey the most relevant information. The effect in symptom studies shows up as lower retrospective discomfort ratings when, for example, pain or dyspnea ended gradually at a lower discomfort level rather than abruptly at the peak, despite an equal level of peak discomfort and a longer duration of total discomfort (Kahneman et al., 1993; Bogaerts et al., 2012). Interestingly, patients with MUS do not show this effect, suggesting substantial differences in the way they represent symptom episodes in memory (Bogaerts et al., 2012).

In general, it can be concluded that research on memory for symptoms needs more attention in view of its importance for diagnostic and therapeutic assessment of self-reported health.

Medically Unexplained Symptoms: A Symptom Perception Pathology?

For a substantial part of the patients consulting medical doctors, no physiological dysfunction can be related to their health complaints. Hence, the latter are often called MUS. The share of MUS in primary care consultations is estimated to range from 20 up to 50%, while prevalence rates in secondary care are even higher (Nimnuan et al., 2001). Typical symptoms are fatigue, weakness, headache, muscle aches, nausea and other gastrointestinal complaints, joint pain, palpitations, chest pain, dyspnea, dizziness, etc. (Barsky and Borus, 1999) In a clinical context, the symptoms often appear as functional syndromes, such as chronic fatigue, fibromyalgia, irritable bowel disease, multiple chemical sensitivity, etc. Despite specific diagnostic criteria for such syndromes, overlap and comorbidity between the different categories is large, leading to a debate between 'lumpers' (who consider the different syndromes as basically identical) and 'splitters' (who emphasize the different specificities of the syndromes) (Wessely et al., 1999; Lacourt et al., 2013; White, 2010).

MUS challenge the traditional disease model, which assumes a direct relationship between a physiological dysfunction and self-reported complaints. The absence of such a relationship is the source of both frustrated medical doctors and patients, it feeds somatization processes in the patient and leads to overuse of health care resources and puts a substantial burden on the health care system (Barsky et al., 2005).

Several strategies are followed in search of an explanation. One strategy is motivated by the assumption that as yet unknown (stress-related?) dysfunction in peripheral physiological systems and/or in their interaction with the brain, such as the immune-to-brain communication, is critical and that symptom reports are a true reflection of such dysfunctions. Several reviews revealed evidence in support of this strategy, but the critical involvement of specific physiological systems is overall not considered convincing enough because of the lack of evidence documenting the specificity, consistency, and/or causal direction of the findings (Rief and Barsky, 2005). Other strategies rely on the idea that the critical mechanisms are centrally mediated distortions in the perception of one's bodily state. While substantial evidence is consistently showing distortions in perceptual-cognitive mechanisms of symptom perception, cause–effect relationships remain often unclear, and the critical hypothesized mechanisms remain untested (Rief and Broadbent, 2007).

Both strategies are neither mutually exclusive nor theoretically incompatible. The important advances in placebo research of the recent decade illustrate how deeply psychological variables, such as learning, anticipation, and social context are intertwined with central and peripheral physiological mechanisms (Benedetti, 2013). Such advances are likely the prelude of a paradigm shift in which the opposition between psychological and physiological processes in the study of MUS is considered elusive and will be replaced by research and theorizing on MUS as a nocebo phenomenon, emerging from an intricately intertwined mind-body system.

Conclusion

Several processes modulate the relationship between peripheral physiologic dysfunction and self-reported symptoms. In extreme cases, there is no link at all. This is insufficiently recognized in a biomedical disease model, which assumes a direct relationship between peripheral dysfunction and symptom reports. A more advanced symptom model (Kroenke and Harris, 2001), in which both peripheral and central/psychological processes are included in both a diagnostic and therapeutic step, is needed to further improve health care.

Abstract

Learning and memory are fundamental higher brain functions that allow individuals to adapt to the environment, build up their own history as unique creatures, and widen the personal cultural background, and, ultimately, the population culture. The molecular and cellular mechanisms that contribute to short- and long-term memory are extremely conserved across evolution from mollusks to man and among various forms of memory and consist short- to long-lived rearrangements in synaptic efficiency and in the structure of neuronal networks.

Introduction

Memory is commonly seen as a positive ability of the individual to improve performance, indispensable for survival and social success. Forgetting, on the other hand, generally has a negative connotation, which is often associated with pathological states and/or aging (Della Sala, 2010). This common view is also reflected in our knowledge of the underlying biological processes. Memory and forgetting are daily processes of our life, which allow us to select, from billions of experiences, the most relevant for our personal history and our culture. The French psychobiologist Henry Laborit (1914–95) said that "Without the memories of what was pleasant or unpleasant, it is not possible to be happy, sad, anguished, one cannot get angry, infatuated. One could say that an organism is a memory that acts."

On the other hand, in the absence of forgetting, memory would be completely useless. This concept is very well exemplified by the short fantasy story '*Funes el memorioso*' by Jorge Luis Borges (1942). Describing Funes, Borges says: "On falling from the horse, he lost consciousness; when he recovered it, the present was almost intolerable it was so rich and bright; the same was true of the most ancient and most trivial memories. …And now, his perception and his memory were infallible. …Without effort, he had learned English, French, Portuguese, Latin. I suspect, nevertheless, that he was not very capable of thought. To think is to forget a difference, to generalize, to abstract. In the overly replete world of Funes there were nothing but details, almost contiguous details. …It occurred to me that each one of my words (each one of my gestures) would live on in his implacable memory; I was benumbed by the fear of multiplying superfluous gestures."

The inability to forget details prevents the process of generalization that is necessary for abstract thought and ultimately for making sense of our experiences.

The Synaptic Bases of Learning and Memory

The major and most distinctive feature of the nervous system is its astonishing ability to adapt to the environment and to improve its performance over time and experience. In 1906 this special/unique property, collectively named 'plasticity,' was precisely defined by Santiago Ramon y Cajal as "the property by virtue of which sustained functional changes occur in particular neuronal systems following the administration of appropriate environmental stimuli or the combination of different stimuli." Since the neural changes evoked by the stimuli can persist for a very long time, virtually for the whole life of the individual, neural plasticity could represent an attractive basis for learning and memory. Conversely, the built-in property of neural plasticity might allow experience to functionally and structurally shape the nervous system. The latter aspect, which is also a fundamental feature of neural development and maturation, was envisaged in the third century BC by the Greek philosopher Epicurus who wrote that "it's because something of the external objects penetrates in ourselves that we can identify shapes and think."

The first assembly of neuronal networks is driven by genetic factors, i.e., by the size of the physiological targets and the expression of chemotactic and/or cell adhesion 'recognition' proteins whose genes are specifically transcribed and translated by the various neuronal populations (Kandel et al., 2012). After this first gene-driven developmental period, neuronal circuits are continuously modified and shaped by experience (epigenetic development): synaptic connections that are scarcely used become weaker and eventually disappear, whereas synapses that are heavily used become stronger and eventually increase in number. Synaptic strength can be finely tuned over a short or even a long timescale by a combination of factors including previous activity of the network, generation of second messengers, functional changes in pre- and postsynaptic proteins, as well as regulation of the expression of genes implicated in growth, survival, and synaptic transmission. This results in changes in the efficiency of synaptic transmission that can last from a fraction of a second to minutes in the case of short-term synaptic plasticity (facilitation or depression) to hours, days, and months in the case of long-term synaptic plasticity (long-term potentiation (LTP), long-term depression (LTD)). These changes profoundly affect the processing carried out between input and output information and, ultimately, filter and shape the flow of information within the neural network.

Interestingly, after the cornerstone discoveries of Camillo Golgi and Santiago Ramon y Cajal, but some 50 years before Donald Hebb (1949) formulated the idea of synaptic plasticity as the basis of psychological functions, Sigmund Freud proposed in his *Entwurf einer Psychologie* (1895) that the physical structure of memories consists of a long-lasting activity-dependent modification of information transfer between neurons (Freud, 1953; Sejnowski, 1999; Centonze et al., 2004). Freud drew attention to the synapse, which he called 'contact barrier,' and to the quantity of information '$Q\eta$' that passes through the synapse during the process of neural excitation, i.e., the equivalent of synaptic strength (**Figure 1**). He identified two types of communication, that of "permeable or φ neurons that behave as if they have no contact barriers" (i.e., neurons which transfer information across the synapse without resistance) and that of "impermeabile or ψ neurons which act in such a way as to permit only a difficult or partial passage of $Q\eta$." Thus, the activity of a network depends on the mosaic of facilitated and nonfacilitated barriers since, as Freud says, "$Q\eta$ in an α neuron will be directed toward a more facilitated barrier… and the higher $Q\eta$ during the course of excitation, the greater the facilitation." Thus, memories can be represented as sequences of activity patterns distributed across a population of neurons, which in turn are associated with a different subsequent pattern of encoding (**Figure 1**). During retrieval, a memory cue may cause neural activity to evolve toward one of these activity patterns (attractor state; Hasselmo and McClelland, 1999).

Figure 1 The synapse is at the basis of learning and memory. Upper panel: Sigmund Freud's drawing describing the possibility that changes in the gain of synaptic connections in a neuronal network are at the basis of learning and memory. Middle panel: Two large hippocampal neurons in culture (stained in green) receiving multiple synaptic inputs labeled for the presynaptic protein synaptophysin (red puncta). Lower panel: Three-dimensional reconstruction of an axon terminal from a chemical synapse with its complement of synaptic vesicles storing and releasing neurotransmitter (courtesy of Andrea Raimondi, IIT, Genova).

Memory Consolidation at the Cellular Level

Learning induces cellular and molecular changes that facilitate or impair communication among neurons and are fundamental for memory storage. If learning brings about changes in 'synaptic strength' within neuronal circuits, the persistence of these changes represents the way memories are stored. Short-term memory is believed to involve only functional changes in pre-existing neuronal networks, mediated by a fine-tuning of multiple intracellular signal transductions systems. These short-lived changes can undergo either of two processes: either fade out with time (forgetfulness) or be reinforced and transformed into long-term memory by a process called memory consolidation. Forgetfulness is at least as important as consolidation. Since only a minimal part of what we perceive is useful, the brain needs a mechanism to prevent itself from being burdened by negligible information. To be consolidated, functional changes have to be followed by gene transcription and protein synthesis that produce permanent phenotypic changes in the neuron associated with structural rearrangements in neuronal networks. Thus, memory consolidation is abolished by mRNA and protein synthesis inhibitors. Consolidation is not a high fidelity process: stored memories gradually change and fade with time and only the most relevant and useful aspects are retained over time (Kandel and Pittenger, 1999; Silva and Josselyn, 2002).

Several molecular actors and biochemical processes underlie short-term memory processes. Two processes that appear to be a final common pathway are phosphorylation and dephosphorylation of synaptic proteins (Greengard et al., 1993; Greengard, 2001). Phosphorylation has dramatic effects on protein conformation, interactions, and functions. Thus, the balance between phosphorylation and dephosphorylation is tightly regulated in neurons via the activation of kinase and phosphatase enzymes by specific intracellular signaling molecules called 'second messengers' that include cyclic AMP and calcium. The finely tuned balance between phosphorylation and dephosphorylation has a strong impact on synaptic transmission both at the presynaptic level (neurotransmitter release) and at the postsynaptic level (density and affinity of receptors, activation of signal transduction systems, generation of

retrograde messengers). The activation of the molecules involved in these signaling pathways can last for minutes and thereby represents a sort of short-term 'molecular memory' which can operate as a '*push–pull*' mechanism playing a key role in regulating the delicate balance between storage and disposal of short-term memories (Greengard et al., 1993; Elgersma and Silva, 1999; Abel and Lattal, 2001; Silva and Josselyn, 2002; Genoux et al., 2002).

These purely functional changes cannot survive for long times in the absence of a structural rearrangement of the neurons participating in the modulated synapse. The sustained activation of the same pathways promotes memory consolidation by affecting gene transcription and translation. Sustained stimulation leads to persistent activation of the cyclic AMP-dependent protein kinase and the extracellular signal-regulated kinase pathways. In turn, the cyclic AMP-dependent protein kinase phosphorylates and activates the transcriptional activator CREB1a, whereas the extracellular signal-regulated kinase phosphorylates and inactivates the transcriptional repressor CREB2. The CREB family of transcription regulators is highly conserved across evolution and represents the major switch involved in the transformation of short-term memory into long-term memory. The CREB target genes, whose transcription is regulated during consolidation, include a set of immediate-early genes (such as C/EBP or *zif*268) that affect transcription of downstream genes. This results in changes, either increases or decreases, in the expression of an array of proteins involved in protein synthesis, axon growth, synaptic structure, and function (Kandel and Pittenger, 1999; Alberini, 2005; Bozon et al., 2003). When synaptic strength has to be permanently potentiated (LTP), ribosomal proteins, neurotrophins, Ca^{2+}-binding proteins, and proteins involved in the exo–endocytic cycle of synaptic vesicles and neurotransmitter receptors become upregulated, whereas cell adhesion molecules that usually maintain synaptic stability become downregulated. These specific changes in protein expression favor growth of terminal axon branches and establishments of novel synaptic contacts. Opposite phenomena are believed to occur in the case of LTD of synaptic strength, favoring a decrease in the number of synaptic connections and/or a decreased activity of the existing synapses.

Such properties of synapses were remarkably emphasized by Donald Hebb. He wrote: "when an axon of cell A is near enough to excite cell B or repeatedly or consistently takes part in firing it, some growth or metabolic change takes place in one or both cells such that A's efficiency, as one of the cells firing B, is increased" (Hebb, 1949; Sejnowski, 1999). In other words, a '*synaptic learning rule*' exists by which synapses learn from the pattern of afferent stimulation and persistently change synaptic strength accordingly (**Figure 2**). Although LTP and LTD were originally referred to specific synapses (in the hippocampus and the cerebellum, respectively), it turned out that virtually every synapse can finely tune its strength entering a potentiated or depressed state that can last for long

Figure 2 Plasticity paradigms as a '*synaptic learning rule*.' Upper panels: Long-term potentiation (LTP) and long-term depression (LTD) in the dentate gyrus of the hippocampus. Point plot representing the magnitude synaptic in awake rats evoked once every minute. Lower panel: Bidirectional modification of synaptic plasticity as a function of frequency and correlation of the presynaptic activity.

periods of time. As Albert Einstein wrote: "The mind that opens up to a new idea, never comes back to the previous state."

Distinct Forms of Memory Share Similar Cellular Mechanisms

Two major types of memory exist, one for skills and one for knowledge. The first one refers to information storage to perform various reflexive or perceptual tasks and is also referred to as nondeclarative or implicit memory because it is recalled unconsciously. The second form of memory, called declarative or explicit memory because it is recalled by a deliberate and conscious effort, concerns factual knowledge of persons, things, notions, and places. Declarative memory can be further subdivided into episodic or autobiographic memory and semantic memory.

Neuropsychological studies, pioneered by the Canadian neuropsychologist Brenda Milner, have shown that the multiple memory systems involve distinct brain areas and exhibit distinctive features. Thus, explicit memory requires an intact medial temporal lobe (hippocampus), while implicit memory systems are integrated at various levels in the central nervous system including reflex pathways, striatum, cerebellum, amygdala, and neocortex. Moreover, the kinetics of the learning, consolidation, and recall phases of memories are quite different. Implicit memory, e.g., learning to ride a bike, takes time and many attempts to build up, while explicit memory, such as learning a page of history or a telephone number, is more immediate and implies a smaller effort. However, while explicit memory fades relatively rapidly in the absence of recall and refreshing, implicit memory is much more robust and may last for all our life even in the absence of further practice (Blackemore, 1977; Kandel and Pittenger, 1999).

The simplest paradigms of implicit memory are elementary forms of nonassociative and associative behaviors, which are present in primitive animals. These paradigms have been effectively studied in mollusks, particularly the sea snail *Aplysia californica*, which has a very simple central nervous system made up of a few thousand neurons (the human brain in comparison is made up of about 10^{11}–10^{12} neurons). *Aplysia* is able to learn specific behaviors that, upon practice, can be consolidated into long-term memories. The animal progressively learns to respond more weakly to repeated innocuous stimuli (e.g., a light tactile stimulus), a behavior called *habituation*, and to reinforce the response to repeated noxious stimuli (e.g., a painful electrical shock), a behavior known as *sensitization*. In both cases, the synaptic efficiency in the integration center of a sensory-motor reflex is changed by experience, leading to an increased response of the reflex in the case of sensitization or to a reflex inhibition in the case of habituation. Both changes are integrated at the presynaptic level, mediated by changes in calcium influx in response to the action potential. In habituation, calcium influx is decreased into the sensory neuron terminal, resulting in depression of glutamate release. In sensitization, on the other hand, the activity of a facilitating serotonergic interneuron induces phosphorylation of a potassium channel and lengthening of the depolarization, thus increasing the influx of calcium and the release of glutamate (facilitation; Kandel and Pittenger, 1999; Kandel et al., 2012).

Aplysia also exhibits a more complex form of associative learning, typical of higher animals, known as classical conditioning. In this learning paradigm, the animal is given a strong and painful unconditioned stimulus (that if administered alone would produce sensitization) in association with a weak, innocuous, conditioned stimulus (that if administered alone would produce habituation). Following the repeated pairing of these two stimuli over the trials, the animal learns to associate the two stimuli and to react to the isolated conditioned stimulus with an enhanced response (greater than sensitization to the noxious stimulus). Classical conditioning is reflected in the neural circuitry as a greatly enhanced synaptic strength of the input connections between the sensory neuron and the motor neuron. In contrast to nonconditioned learning, this potentiation involves both presynaptic and postsynaptic mechanisms. The coincidence of the two stimuli is revealed by specific coincidence detectors located on both sides of the synapse and including adenylyl cyclase at the presynaptic level, and the ligand- and voltage-operated *N*-methyl-D-aspartate (NMDA)-type glutamate receptor at the postsynaptic level (Kandel and Pittenger, 1999; Kandel et al., 2012). This simple model, highly conserved phylogenetically, tells us that association of events, sensed by synaptic coincidence detectors, generates long-term synaptic changes (such as LTP) that maintain the associative memory with time.

The studies on the mechanisms involved in explicit memory are more complex, as explicit memory involves conscious recall and the integration of multiple sensory inputs. Thus, these studies are not feasible in invertebrates and lower vertebrates but instead require the complexity of the mammalian nervous system. Experimental work in rodents and man has provided strong evidence for the involvement of the hippocampus in many kinds of explicit memory, and particularly in spatial memory. The famous case of Henry Gustav Molaison (the patient H.M.; 1926–2008), who underwent a bilateral hippocampectomy in 1953 to cure an intractable form of epilepsy, first revealed that in the absence of the hippocampus we lose the ability to consolidate new explicit memories. Interestingly, in H.M., short-term memory, old explicit memories, and implicit memory processes were completely normal. The intuition by Brenda Milner on the role of hippocampus in the consolidation of new explicit memories was later confirmed by functional magnetic resonance imaging studies, which have demonstrated an activation of the medial temporal lobe in all tasks in which the subject memorizes a map or mentally rehearses an itinerary. Moreover, studies on the rodent hippocampus have revealed the existence of '*place cells*,' whose firing is primarily controlled by the position of the animal and by distant visual cues that create an internal representation of the animal's location with respect to the surrounding environment (Colgin et al., 2008). In analogy with the rodent 'place cells,' which are very selective and, from a very low baseline, fire strongly to their preferred stimulus, giving an explicit representation of the environment, recording of multiple single neurons in awake and behaving human subjects has shown that sparse neurons in the human medial temporal lobe (and particularly in the hippocampus) respond in a remarkably selective and abstract manner to particular

persons or objects, such as *Jennifer Aniston*, *Luke Skywalker*, or the *Tower of Pisa*. These neurons have been named 'Jennifer Aniston neurons' or, more recently, 'concept cells.' Concept cells can be activated by multiple sensory modalities and encode an abstract representation of the concept triggered by the stimulus. These neurons are probably not required for memory per se, but are crucial for the creation of associations that lead episodic memories and the flow of consciousness (Quiroga, 2012).

The key role of the hippocampus in the formation of new explicit memories and the fact that this brain area exhibits the most known and extensively studied form of synaptic plasticity, namely LTP, has directed research toward the demonstration of a direct link between LTP and memory (Kandel and Pittenger, 1999; Kandel et al., 2012; Moser and Paulsen, 2001; Colgin et al., 2008). A large number of studies have demonstrated that LTP is indeed a valid model of 'memory storage': hippocampal LTP can be induced by animal experience and, conversely, conscious learning is impaired under conditions in which LTP is impaired or abolished. LTP has all the features required to be the cellular mechanism of explicit memory as it is associative in nature, is triggered by the coincidence of events and can be activated by endogenous patterns of electrical activity (e.g., the Θ rhythm). The molecular mechanisms that mediate the generation of hippocampal LTP are surprisingly conserved across evolution and are closely similar to the mechanisms of associative learning identified in invertebrates. Thus, both pre- and postsynaptic mechanisms participate in the early phase of LTP expression, with a coincidence detector represented in most cases by NMDA-type glutamate receptors that trigger activation of multiple kinase pathways, including calcium/calmodulin dependent kinases, and generation of retrograde messengers. Moreover, the late phase of LTP involves activation of transcription factors (*CREB*, *C/EBPβ*, *Arc*, *c-fos*, etc.) and regulation of transcription of the target genes (Miller and Mayford, 1999; Matynia et al., 2002; Alberini, 2005, 2008, 2009; Won and Silva, 2008; Miyashita et al., 2008).

Memory needs time to be stabilized in the hippocampus before the final storage. In fact, LTP induced by an experience is inhibited by a novel experience administered soon after the first one (interference), whereas an LTP established for more than 1 h is immune to this reversal mechanism. These observations suggest that the critical event in determining the retention of information may consist in the stabilization of the potentiated hippocampal synapses in order to resist the LTP reversal upon new information (Miller and Mayford, 1999). Although the hippocampus is fundamental to the acquisition of new memories, it appears to be dispensable after the memory has been fully consolidated. Although patient H.M. was totally unable to lay down new memories, he was still able to remember his past life preceding the bilateral ablation of the hippocampi. This indicates that permanent memories are distributed among different cortical regions according to the various perceptual features ('feature map') and that these various aspects are linked in a 'master map' so that, upon recall, the different components of a memory are bound together to reproduce the memory in its integrity (Seung, 2009). It is currently believed that this memory transfer process occurs largely during sleep, particularly the rapid eye movement phase of sleep (Kandel and Pittenger, 1999; Alberini, 2005). Thus, the hippocampus may represent both the site of the imprinting of the memory and the temporary store for this trace during the progressive formation of neocortical memory representations (Hasselmo and McClelland, 1999).

Memory Recall and Reconsolidation

Upon new learning, a short-lived memory is formed that can be either stabilized over the following several hours or pruned out. If this consolidation process takes place, a long-term memory is formed that is thought to be rather stable over time and stored as permanent modifications in the wiring of the brain in modality-specific areas. Traditionally, consolidation has been considered as an event occurring only once in the biological history of a memory, and recall of a given memory has been often considered a good exercise against forgetting. However, it has only recently become clear that retrieval does not directly reinvigorate memories, rather it makes them return to a labile state susceptible to disruption and interference which needs further consolidation (the so-called reconsolidation process).

This process, originally proposed in the 1960s (Lewis, 1979), has only been recently studied in detail. Reconsolidation appears to be a highly dynamic process that occurs every time memories are reactivated. From a general point of view, consolidation and reconsolidation should be considered as part of the fundamental process of memory stabilization that allows a memory to be preserved, recalled, refreshed over the years. It is commonly found that memories do not remain unchanged over time, but that they undergo transformations in their basic elements and emotional content that have nothing to do with fading. This phenomenon implies that consolidation that is carried out soon after the salient experience cannot be the unique mechanism involved. Rather, reconsolidation provides a dynamic mechanism for updating and modifying memories while they are recalled. What is a bit counterintuitive in this general scheme of memory processes is that a stable memory goes back to a labile state when it is recalled, that is to say that memory recalling is per se an amnesic challenge. However, as memories are not printed as tracks in a compact disk, but are dynamically stored as changes in activity patterns in networks of neurons which in turn depend on modulation of synaptic strength, it is understandable that reactivation of these activity patterns during recall may change the plastic substrate of the memory, so that additional plasticity changes are needed to preserve it. Moreover, the temporal dynamics and the extent by which a memory is deconsolidated upon retrieval strongly depend on the strength of the initially consolidated trace, on the intensity of reactivation, and on the number of reactivation episodes over time. As a general rule, stronger memories are less susceptible to forgetfulness, and the stronger the reactivation, the more labile the memory becomes. It is as if reactivation subtracts part of the memory body and the subtracted part has to be 'rebuilt' by reconsolidation.

Moreover, although every time a memory is reactivated, it regresses to a labile state and needs reconsolidation; each successive reactivation task requires a progressively smaller reconsolidation. The memory therefore becomes rather stable after several cycles, and successive retrieval episodes will not disrupt the trace; the respective reconsolidation episodes will only modify it (Nader, 2003a,b; Dudai and Eisenberg, 2004).

As mentioned earlier, consolidation (i.e., the transformation of short-term memory into long-term memory) requires transcription of specific genes and protein synthesis and involves an array of highly conserved signaling pathways including calcium, cyclic AMP, cyclic AMP-dependent and extracellular signal-regulated kinases, as well as tyrosine kinases that collectively render the memory resistant to cell turnover. Distinct areas are engaged over time in a precise temporal and spatial sequence at both cellular and systems levels. It is well known that hippocampus-related memories are hippocampus-dependent only over a limited period and that at later times they become hippocampus-independent (remote memories), indicating that other brain regions connected to the hippocampus have undergone a sequential memory imprinting (Nader, 2003a; Nader and Hardt, 2009).

When the memory is reactivated, it regresses to a short-term memory labile state (*postreactivation* short-term memory) that is again hippocampus-dependent and sensitive to interference. Thus, the memory needs to be reconsolidated in order to become *postreactivation* long-term memory. However, if the memory is not reactivated, it will remain in a stable state that will slowly fade away over time. Thus, recall appears to disrupt this process of slow decay of long-term memory. While the exact mechanisms of recall are not fully understood, reconsolidation has been thoroughly studied by the use of transcription or translation inhibitors or of genetically altered mice lacking specific proteins involved in synaptic plasticity. The most conservative mechanism that can be envisaged for memory reconsolidation is that this process employs the very same molecular mechanisms used for consolidation of short-term memory and that both cellular and systems reconsolidation processes occur. Under conditions of inhibition of protein synthesis, the functional and structural changes that mediate long-term memory become either dysfunctional or actively removed in 4–24 h after reactivation (Alberini, 2005; Nader and Hardt, 2009).

Reconsolidation has been found to occur in many species from invertebrates to vertebrates (including mammals) and therefore represents a highly conserved fundamental process in memory storage. A typical experiment is the following (**Figure 3**). An animal is subjected to a classical conditioning trial and, after the memory is fully stabilized, it is exposed to the conditioning stimulus to reactivate the memory. If the animal is treated with the protein synthesis inhibitor anisomycin in the reactivation session, it exhibits an intact *postreactivation* short-term memory, but the *postreactivation* long-term memory is markedly impaired. Interestingly, if the animal is not challenged for memory reactivation, protein inhibition is ineffective on the long-term memory acquired in the conditioning session, demonstrating that only the reactivated memory becomes sensitive to disruption, unless synthesis of new proteins is allowed.

The sensitivity to protein inhibition applies only to a narrow time window: if the anisomycin 'amnesic' treatment is

Figure 3 Properties of consolidation and reconsolidation of memories. (a) Model of consolidation of short-term memory (STM) to long-term memory (LTM). (b) Blockade of consolidation of a fear memory by administration of anisomycin after conditioning. The treatment does not affect short-term memory, but strongly impairs long-term memory. (c, d) Model of long-term memory reconsolidation. Long-term memory and post-reactivation long-term memory (PR-LTM) are stable traces in an inactive state. Reactivated memories return in an active, labile state that needs reconsolidation for long-term storage.

administered several hours after reactivation, it is ineffective, indicating that reconsolidation, like consolidation, is a time-dependent mechanism and that the time needed for reconsolidation is generally shorter than that needed for consolidation. This picture was observed in the case of diverse memory paradigms, including contextual or fear conditioning, passive avoidance, object recognition, taste aversion, motor sequence learning, etc. As for consolidation, reconsolidation is not demonstrated only in behavioral tasks, but it also has neurophysiological correlates. It has been demonstrated that if anisomycin is given 2 h after LTP induction, it does not affect LTP maintenance. The most conservative explanation is that both consolidation and reconsolidation share the same mechanisms of synaptic rearrangement and permanent tuning of the strength of synaptic connections. Indeed, this seems to be often the case, although similarities between the two processes are not complete and important differences exist in either the molecular actors involved or in the target brain regions or both (Nader, 2003a; Alberini, 2005; Nader and Hardt, 2009).

Recent data have shown that in humans existing declarative memories can be selectively rewritten by disrupting reconsolidation using a noninvasive retrieval–relearning technique. This reconsolidation-associated amnesia can be achieved 48 h after formation of the original memory, but only if relearning occurs soon after retrieval (Chan and LaPaglia, 2013). These results demonstrate that also declarative memories, whose encoding and retrieval rely on a distributed network, are susceptible to reactivation-induced lability, and that memory impairment can be obtained in a behavioral paradigm, without the use of pharmacological agents.

In conclusion, memory recall destabilizes long-term memory and poses the need for memory reconsolidation. Successive cycles of reconsolidation make the memory more stable, even in the presence of successive retrievals and, at the same time, rearrange and slowly modify the memory trace, so that the most salient and emotionally significant features are preserved or even enhanced (Figure 4). Consolidation and reconsolidation often occur in distinct brain regions or subregions, consistent with the idea that consolidated memories are sorted to diverse brain areas, but the molecular mechanisms involved largely overlap.

Conclusions

Memory is not just an ability to store information, but the essence of our beings, the basis of our individuality and our consciousness. Each individual knows that he/she is unique, not merely because of his/her external appearance, but because of his/her personal history, behavior, and ability to face daily life. Learning and memory are achieved by permanently shaping neuronal circuits and interneuronal connections. These modifications are initially labile, but if they are perceived as useful and salient, then they are consolidated and eventually reconsolidated to become a stable memory. However, most of the percept is quickly discarded, in a process of selection: what we think is relevant is remembered, although it tends to fade and change with time: "Life is not what one lived, but what one remembers and how one remembers it in order to recount it. The heart's memory eliminates the bad and magnifies the good; and thanks to this artifice we manage to endure the burdens of the past" Gabriel Garcia Marquez said (Marquez, 2002). Although many questions remain open, the astonishing progress in the field of molecular and cellular neuroscience is greatly contributing to the understanding of the exact role of

Figure 4 Lifetime and transformations of memory traces. Once short-term memories have been consolidated into long-term memories, they will slowly fade away if not recalled. On the contrary, if recalled, long-term memories are destabilized and need a process of reconsolidation to be preserved. Successive cycles of recall and reconsolidation make the memory more stable, but, at the same time, rearrange and progressively modify the memory trace.

gene products and signaling pathways in distinct processes of memory and forgetting, and it is likely that within a few years this knowledge will be translated into the development of novel therapeutic approaches to memory disorders.

Syncretism

André Droogers, Vrije Universiteit, Amsterdam, The Netherlands

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The meaning of the term 'syncretism' has changed drastically over the course of time. Currently, the term refers to the mixing together of elements from different religions. This mixing is sometimes viewed with contempt, especially by the clergy of the religions concerned. Scholarly use of the term is more objective and does not entail this kind of value judgment. In this article we will describe the history of the term. Special attention will be given to current debates on power mechanisms in syncretism. Syncretism will be compared with fundamentalism. Finally, the tendency to move on from defining syncretism to studying the process of syncretization will be discussed.

History of the Term 'Syncretism'

Earliest Uses

The first known use of the term 'syncretism' is found in Plutarch's (46?–125) *Moralia* (Morals), a treatise on moral principles. When suggesting that one should consider one's brother's enemies and friends as one's own enemies and friends, he uses the example of the inhabitants of Crete. Plutarch uses the word syncretism to refer to their habit of forgetting internal conflicts and differences when confronting a common enemy. It may be that the use of the word was inspired not only by the Cretans' example but also by a word play, since the Greek *syngkrasis* means a 'mixing together' (Stewart and Shaw, 1994: p.3).

The second author known to have used the term was the humanist Erasmus of Rotterdam (1496–1536). He quoted Plutarch and, like him, recommended syncretism, although here as a way of seeking a synthesis of seemingly disparate philosophical and theological opinions and as an attempt to understand the other completely, despite differences of view.

After the Reformation, with its increase in divergent theological views, the term acquired a negative connotation for the first time. Opponents of the Danish–German Lutheran theologian George Calixtus (1586–1656), an early defendant of ecumenism and theological reconciliation, used the term pejoratively as a mixing of points of view that, in their opinion, was to be avoided. The debate became known as the 'syncretistic controversy.'

Views from Religious Studies and Missionary Practice

In the nineteenth century, when research on world religions began to flourish and colonialism brought cultures and religions into contact, syncretism was understood more objectively as the mixing of elements from different religions, although purity continued to be viewed implicitly as the norm (Rudolph, 1979: pp.196–197).

Christianity also reached the height of its expansion in the nineteenth century. Missionaries objected to the tendency of new converts to continue practices from their prior religion. Syncretism then became the concept used for this – condemned and combated – tendency. This meant that Christian theological use of the term was no longer restricted to internal differences between theologians but referred to the mixing of religious elements, especially Christian and non-Christian. Unlike its usage in religious studies, syncretism was considered impure, contradictory, and inconsistent, and therefore censurable and illegitimate. The term still retains this meaning, even though ecumenical missionary circles have become more understanding of the need to translate the Christian message into local cultural terms (so-called inculturation; see Schreiter, 1993). It has also been suggested that Christianity itself is the result of a syncretistic process (Pannenberg, 1970: pp.85–88 and note 37). Yet, despite this development, the theological criterion continues to be how intact the core message of Christianity remains. An exception is the Korean theologian Chung Hyun-Kyung, known for her address to the Assembly of the World Council of Churches in Canberra in 1991.

For a long time, scholars in religious studies have worked with the term and defined its meanings (Rudolph, 1979 offers a useful summary), whereas, as will be shown in the next section, the term has a much shorter history in anthropology. Scholars in the field of religious studies, such as historians and phenomenologists of religion, view syncretism objectively and point to its general presence at the founding of religions (even in religions that now oppose syncretism; cf. Maroney, 2006) and in their mutual contact. Scholars distinguish between symmetrical and equal relationships between religions on the one hand, with mutual exchange, and asymmetrical and unequal relationships on the other hand, with unilateral influencing. The basic ambiguity of meanings in syncretistic contexts has been emphasized by Pye (1971: p.93). Typologies of the degree to which elements can be mixed have been proposed, using terms such as 'identification,' 'amalgamation,' and 'symbiosis.' It has been acknowledged that syncretism may involve elements other than religious ones, because religions are linked to cultural contexts. Syncretism then appears as a religious form of a general cultural process of meaning-making. Sometimes, syncretism is presented as the result but more often as the process itself.

Whereas syncretistic clergy is more the exception than the rule, syncretism can be found as a normal part of popular religion, generally condemned by the representatives of official religion. Correspondingly, syncretism has often been depicted as an unconscious, implicit, and spontaneous routine, as typical of what Redfield called the little tradition of the

unreflective many (Rudolph, 1979: p.208). In terms of Saussure's linguistic distinction between *langue* (the system) and *parole* (speech), institutional religion resembles the first, whereas syncretism can be compared to the latter (Leopold and Jensen, 2004: pp.381–382).

There have also been proposals to excise the term from scholarly vocabulary (Baird, 1971; Pakkanen, 1996; Schineller, 1992; Van der Veer, 1994), for being too vague, subjective, and too broad. If syncretism occurs in all religions and if borrowing and blending are universals in any event, the term seems to be insufficiently specific and therefore superfluous. But the term 'syncretism' is useful for showing the relativity of established and rather essentialist categories, such as 'world religion,' 'tribal religion,' or 'big and little tradition.' The focus could move from bounded institutionalized systems of beliefs and practices to the individual believer who is finding his or her way through these systems, not only between religions but also within one religion, and including the wider cultural context. Whereas institutionalized forms of religion can be easily located and studied, the individual syncretistic believer, including his or her idiosyncratic practice of plural meaning-making, is not as easily researched.

Precise definition or even redefinition may further the debate on the use of the concept (see Leopold and Jensen, 2004 for a fundamental discussion of the issues and options at stake). In view of the increase in contact between believers of different religions, some term is needed to refer to the inevitable mixing of religious elements. In addition, the long history of the term has shown that its meaning is open to change.

Views from Cultural Anthropology

Although students of religion from outside cultural anthropology focused on world religions, the first anthropological texts on syncretism referred to Latin American and Caribbean examples, especially the Afro-Christian syncretism that followed from the presence of slaves and their descendants in the region. Of course, syncretism was present in other areas, but where the negative missionary use of the term was the norm, as in Africa, anthropologists avoided using the term, even with respect to obvious cases of syncretism, as occurred in the so-called African independent churches founded by Africans and not by missionaries (Stewart and Shaw, 1994: pp.14–16).

When the American anthropologist Melville Herskovits began using the term in anthropology, following his Brazilian student Arthur Ramos, he took his examples from Afro-American religions (Greenfield and Droogers, 2001: pp.26–28; Stewart and Shaw, 1994: pp.5–6). His interest in the topic was partly ideological, because he understood syncretism as a tool for promoting a unified culture in the United States, to be formed from the many cultures that immigrants, including those who had involuntarily come from Africa, had brought with them. This melting-pot idea was, of course, a way of rehabilitating the Afro-American strand in the US culture over against white racism. Moreover, Herskovits saw syncretism as a halfway stage in the process of acculturation, the intermingling of cultures in contact. He was very much interested in the way people gave meanings to selected old and new elements, mixing cultural standards, and thus initiating change toward a new synthesis. The alternative course is an emphasis on authenticity and a return to tradition and to the past, as in the case of the black consciousness movement. Nourished by the political ideal of integration the concept of acculturation may have suggested a one-sided linear evolution.

Another scholar who used the term 'syncretism' in the Afro-American context was the French ethnologist Roger Bastide (1978). On the basis of fieldwork in Afro-Brazilian religions, he emphasized the systematic way in which analogous elements from different religious sources are mixed. He also pointed to the role of power mechanisms, especially in the contact between slaves and their masters. The structural similarity between African, Catholic, and Amerindian worldviews facilitated syncretism. Thus, African gods could be identified with Catholic saints and Amerindian spirits. In the oppression that the slaves suffered, supernatural help was most welcome. This redressed the balance of power somewhat, such as when masters were the object of slave rituals intended to harm them. The redress of this balance also became clear when Catholic elements were selectively adopted through the application of African criteria, and not vice versa, as the masters wished when they baptized their slaves. In practice, as a strategic device, identification with and differentiation from the masters' religion were both used in a double game. Thus, the apparent adoption of a Catholic ritual attitude in Mass could serve as an alibi for the continuation of African ritual practices.

One might ask whether syncretism is primarily a matter of convictions and ideas, or of practices and rituals. The fact that syncretists are usually not aware of their mixing attitude points to a trial-and-error integration of new religious ideas and practices in their routine, more in an unconscious, natural way than an emphatic, intercultural way. Because rituals often serve a practical purpose, any new element that promises to be effective will be welcomed, thereby making religious practice the preferred scene for syncretism, as was the case in Afro-American syncretism. Interreligious pilgrimage is another case in point. Those religious leaders who manifest themselves against syncretism may combat either ideas or practices, or both, though the practices are by nature more visible than the ideas. On the other hand, the clergy's theological interest may be more focused on beliefs, especially those that obviously were in contrast with their own doctrine – which served as a sieve. In any case, much syncretism goes in fact unobserved, partly for lack of information on the part of the religious leadership, and partly for not drawing attention, as is especially the case with ideas.

Current Issues

Power

The political use of the concept of syncretism has received more attention in the 1990s (Droogers, 1989; Greenfield and Droogers, 2001; Stewart and Shaw, 1994). The negative sense of the term is an indication of a conflict between clergy and laity on the right to produce legitimate religion. Leaders of a religion whose adepts are involved in a syncretistic process will, from a purist point of view, use their power to condemn any effort to mix elements from different religions as heresy. Stewart and Shaw (1994) accordingly proposed the term 'antisyncretism.'

As suggested earlier in the article, the subjective meaning of the term could be a reason for abandoning the term in scholarly use. Yet it has the advantage of revealing the power dimension of the syncretism process. In that sense, syncretism is one of a number of terms used in anthropology despite their pejorative meanings, such as magic or popular religion, all having the connotation of deviation, resistance, and rebellion. Moreover, religious innovators, including founders of world religions, operated in a manner that can be labeled syncretistic, often being critical of the established religion of their days.

An attitude of antisyncretism is not only held by leaders of affected religions but can also be found in representatives of religions that are the result of a process of syncretism, once these religions have transformed themselves from movement into institution. Thus, some leaders of the very syncretistic Afro-Brazilian religions adopt an antisyncretistic attitude, favoring a return to the African roots and the removal of all Catholic influence.

Syncretism and Fundamentalism

In various senses, syncretism and fundamentalism are opposites (Droogers, 2005, 2008; Maroney, 2006). Whereas syncretism uses more than one religious source, fundamentalism defends the uniqueness of the one source, often codified in a sacred text. Syncretism implies that more versions of the experience with the sacred are acceptable and can be combined, whereas fundamentalists defend one exclusive version. Syncretists experiment with religious symbols, as many as seem to be applicable to their situation, whereas fundamentalists jealously guard the one central symbol of their religion. Syncretism is usually criticized by religious specialists who feel that they are losing control and who may react by defending a fundamentalist view. Syncretists interpret the opportunity offered by the growing contact between cultures and religions as a chance to combine religious repertoires for thought and action, whereas fundamentalists react to the moral side effects of this contact by retreating to the traditional repertoire, even though they may make use of modern means of communication to spread their message. Both syncretism and fundamentalism seem to flourish as a consequence of modernization and globalization but for different reasons: one embracing the new situation, the other being critical of it because it is felt to threaten cherished traditions and morals. Syncretists behave as global citizens, whereas fundamentalists divide the world into 'us' and 'them.' Syncretists are not organized and rarely present themselves as such, whereas fundamentalists tend to organize themselves and to occupy power positions. Syncretists embrace the stream of information on religious ideas and practices produced by modern mass media, whereas fundamentalists tend to view this type of information as inappropriate and therefore to be barred. Syncretists easily admit inconsistencies or are not even aware that they do so, while fundamentalists tend to build a system with its own logic and principles of causality.

From Definition to Process

Whereas for decades the main issue in the debate on syncretism was its definition, more recently the central question has become what actually happens in the syncretistic process. Now that the field of study has been outlined, more attention can be given to the way syncretism works. To reach this point, it was necessary to take leave from an essentialist way of thinking that takes institutional and official religion as the normal and main manifestation of religion, considering deviations from that model as exceptional and even dysfunctional. In fact, though indirectly, scholars for decades copied the religious leadership's perspective and framework. This was reflected in the way syncretism was defined, that is, in contrast to bounded institutional religion. When more attention was given to the way believers deal with the meanings of their beliefs and practices, as happened in the study of popular religion and also by introducing power as a crucial framework in meaning-making, syncretism could become an accepted topic on the research agenda, as normal as institutionalized religion. This also led research from a focus on coherent systems of thought to the process of often inconsistent and complex meaning-making.

This approach was inspired by the increasing tendency to look at culture not as a set of customs connected with a particular society, in the same way as world religions were categorized, but as the universal human capacity for meaning-making. Where formerly culture was the repertoire of meanings that a person should know in order to be able to participate in his or her society, now culture became the tool needed to get along in a globalized world, full of perforated cultural boundaries. Religion could accordingly be understood as a particular form of universal meaning-making, addressing transcendental experiences. The concept of syncretism expressed the same trend in the study of religion. Therewith syncretism became a domain of religious globalization and part of a broader cultural transformation. Similar to the condemnation of religious syncretism by representatives of the clergy in a particular religion, cultural globalization comes with a nationalist or ethnic countermovement, leading to a kind of cultural orthodoxy. The methods used for the study of globalized meaning-making are applicable to the study of syncretism as well. This is also reflected in the more recent interdisciplinary approach in syncretism research, using notions from linguistics and cognitive studies (Leopold and Jensen, 2004). The emphasis on syncretism as deviating from institutional religion becomes less important, whereas its role in the globalization process receives more attention. This also stimulates a view on syncretism as being a normal phenomenon, instead of being a deviation. Its role in the rise and sustenance of institutional religion is acknowledged.

Symptomatic for this development is also the extension of the concept of syncretism to culture in general, as was proposed recently (Adogame et al., 2008). The attention given to the power aspect points in the same direction, showing the political dimension of religion. Parallel to the emphasis on the process, the term then becomes 'syncretization' (Adogame et al., 2008: p.4). This expansion of the study field of syncretism would solve the problem of including or excluding the gray zone of the connections between religious syncretism and the wider social and cultural context. Such an elaboration would put syncretism in one category of concepts with creolization, hybridity, and *bricolage* (on the religious aspects of the latter term, see McGuire and Maduro, 2005),

with a focus on the hermeneutics of blending, negotiating, borrowing, and appropriating. In a way, as a concept, syncretism refers primarily to a form of meaning-making, pointing to religious and, by extension, cultural mixing.

At the same time, the history of the concept is itself an example of ongoing scholarly meaning-making, including the mixing of terms, disciplines, methods, and meanings. Both parties, researchers and researched, appear to be engaged in the same cultural game. Consequently, academia can be said to have its syncretists, just as it has its orthodox and fundamentalist scholars (Droogers, 2008).

Abstract

Fundamental issues in syntax are reviewed including part of speech systems, phrase structures, constituency, grammatical relations, and several syntactic constructions such as possessives, relative clauses, and nominalizations. Chomskyan generative grammar and functional-typological approaches are illustrated and contrasted with reference to several phenomena, including a discussion on a new approach to embedding structures and relative clauses, in particular.

Until the middle of the last century, syntax, along with semantics, was one of the least-developed fields in linguistics. The field, however, witnessed the advent of a new age with the publication of Noam Chomsky's groundbreaking monograph *Syntactic Structures* (1957), which radically altered the outlook on grammar, from individual languages to native speakers' mental knowledge of their languages, and the analytical methods, from the discovery procedures to the positing of deep structures and generative transformational rules, as well as the focus of investigation, from historical comparative linguistics to the theoretical study of the universal properties of human language. Besides these innovations in theoretical linguistics, which have dominated the field over the past 50 years, the 'Chomskyan revolution' aroused interest in syntax-focused descriptions of the world's languages, with the expectations that they would provide empirical foundations for the theoretical inquiries into the nature of human language. In more recent years, however, this latter effort of dovetailing the descriptive-grammar writing and the search for language universals has come to be strongly aligned with the Greenbergian functional-typological, as opposed to the Chomskyan formal, approach to language universals, whose methods are laid out in the influential 1963 paper "Some universals of grammar with particular reference to the order of meaningful elements" by the late Joseph Greenberg. The discussion below scrutinizes some fundamental issues in both theoretical and descriptive studies in syntax in the light of the recent developments in formal and functional-typological approaches to grammar.

Parts of Speech

A grammatical classification of words into lexical categories is prompted by the simple fact that words, the minimal syntactic units, do not behave uniformly. English adjectives, for example, modify a noun, as in *a large dog*, whereas English verbs cannot do so (**a run dog*; cf *a running dog*). Do all languages divide words into similar lexical classes or parts of speech, and if so what are universal parts of speech? These have been perennial questions that have been asked by ancient and modern grammarians alike including Chomskyan generative syntacticians.

Chomsky (1970) proposed feature-based representations of four lexical categories of N, V, A, and P in terms of the specifications of [±N] and [±V] as in (1). The use of features of N and V as basic classificatory features is reminiscent of the ancient division of sentence components into *onoma* (a nominal part) and *rhema* (a verbal part) by Plato (*Cratylus*):

1. N=[+N, –V]
   V=[−N, +V]
   A=[+N, +V]
   P=[−N, –V]

This neat formal representation of parts of speech and its advantages of allowing cross-categorical classifications of words have quickly found their way to syntax textbooks such as Radford (1997: 76), where N, V, A, and P are introduced as 'the four primary lexical categories.' Whether or not this kind of feature notation is adopted, Noun, Verb, Adjective, Preposition, and a few other categories are routinely introduced in textbooks (e.g., Sportiche et al., 2013) that are meant to inform the recent efforts and progress in search of the universal properties of human language.

Similarly, many, if not most, descriptive grammars take it for granted that these lexical categories, or at least so-called open-class categories of noun, verb, adjective, and possibly adverb, exist in all languages and include them without questioning the universal validity of these lexical categories or their realizations in individual languages. While it is unclear what is meant by the characterizations of the four lexical categories given in (1) as the 'major' or 'primary' lexical categories in the works cited above, it is increasingly becoming clear that adjective is not a major or primary lexical category in many languages, and some languages simply do not have prepositions or their positional variants, postpositions (e.g., Dyirbal and other Pama-Nyungan languages in Australian – see Dixon, 2002).

Of A and P (covering both prepositions and postpositions), the problem is more acute for the former since many descriptive grammars assume the existence of an adjective class since languages in general have property-concept words (PCWs) for such semantic categories as size, color, and age, without realizing that parts of speech must be established on morpho-syntactic grounds for each language. While most textbooks offer morphological criteria

such as a tense inflection for verbs, a number inflection for nouns, and comparative and superlative inflections for adjectives, these morphological properties are, for one thing, language specific and are not applicable universally. For another, these morphological features are semantically based, and as such they do not represent the properties of the relevant lexical categories. For example, whether nouns inflect for number or not is determined by the countability of nominal referents, and accordingly there are numerous nouns that do not show the plural inflection in English. Similarly, it is only adjectives denoting gradable property concepts that inflect for the comparative and superlative degrees.

A more reliable method in identifying parts of speech of individual languages is in terms of the morpho-syntactic patterning of lexical items in the three major functional domains of reference, predication, and modification (Croft, 1991). The idea is that those items that display similar morpho-syntactic patterns in the three functional domains form a unified part of speech, while those that pattern differently warrant different lexical classes. In English, nouns and adjectives are similar to a large extent in the ways they behave in both predication and modification functions, and they distinguish themselves from verbs in these functions (see (2a) and (2b)). English nouns differ from adjectives in that while the former can perform a referential function, the latter cannot (2c):

2. a. Predication *This is cotton/expensive/*complain.*
   *They complain/*cotton/*expensive.*
   b. Modification *cotton shirt/expensive shirt/*complain customers.*
   c. Reference *Cotton is a useful commodity.*
   **Expensive is annoying.*

This method of identifying parts of speech also allows cross-linguistic labeling of lexical categories without resorting to the semantic properties of the relevant lexical items. Forms that perform a referential function without undergoing a category-changing derivation are labeled as noun, those that perform a modification function, but not a referential function, without a category-changing derivation form an adjective class, and those that perform a predication function by themselves constitute a verb class. Languages in general have category-changing derivations that permit derived forms to perform functions different from those associated with the relevant lexical categories. For example, English has nominalization processes that convert verbs and adjectives into a nominal category, and these derived nominals behave like basic nouns performing those functions associated with nouns (cf *Smoking* is a bad habit/*Sincerity* is an admirable quality).

One of the limitations of the feature-based analysis of parts of speech like the one shown in (1) is that it fails to capture cross-categorial similarities in a more fine-grained manner. Possible similarities between adjectives and nouns are captured by the shared [+N] specification, and the [+V] specification singles out adjectives and verbs for any cross-categorial similarities they may display. But this system fails to capture the indication seen in (2) above that English adjectives are more similar to nouns than to verbs, a trait that English has inherited from classical Indo-European languages such as Ancient Greek and Sanskrit, and which is more pronounced in Romance and other European languages than in English (see below).

The above point is indicative of the fact that the adjective class is not really a 'major,' 'primary,' or a universal lexical category on a par with the noun and the verb class. While there is a language like Japanese, where PCWs form two adjective classes of verbal adjective (mainly consisting of native PCWs behaving similarly to verbs) and nominal adjective (mainly Chinese loans behaving similarly to nouns), many languages of the world treat PCWs either like nouns, or as a subclass of noun (Quechua, Tarascan (Mexico), Yokuts, Sothern Sierra Miwok, Shaptin, most languages of Europe, North Africa, North Asia, and Australia), or like verbs or as a subclass of verb (many East and Southeast Asian and Pacific languages (e.g., Chinese, Korean, Lahu, and Fijian)) and most of North American languages (e.g., Mohawk) (Dixon 1993; Dixon and Aikhenvald, 2006).

Particularly interesting are languages that divide PCWs into two subclasses of adjectival noun and adjectival verb. The Austronesian language Lamaholot spoken in the eastern tip of Flores Island in eastern Indonesia treats PCWs like *okĩ* 'old,' *wuʔũ* 'new,' *ləmeʔ* 'deep,' *briŋĩ* 'sick,' *blara* 'injured,' *gələ* 'tired,' and so on like nouns in their role in a referential and a modification function, where they can head an NP and can modify another noun without undergoing nominalization. On the other hand, PCWs like *beləʔ* 'big,' *kreʔ* 'small,' *blahaʔ* 'long,' *blolo* 'tall,' *nureʔ* 'young,' *blega* 'wide,' *knipu* 'narrow,' *gə̃* 'sharp,' and so on behave like verbs in that they must be nominalized in order to perform both referential and modification functions (Nagaya, 2011). In Malagasy, another Austronesian language, PCWs like *avaesatora* 'heavy,' *alalaka* 'wide' inflect for present, past, and future tenses just like verbs, while other PCWs like *mandu* 'wet' and *fuhi* 'short' are noun-like in inflecting only for future tense.

Phrase-Structure Rules, Phrasal Categories, and Constituency

In an earlier generative syntax framework, possible syntactic structures of a given language and the constituency (chunking) of the internal phrasal units were defined by phrase-structure (PS) rules of the following form:

3. a. S → NP Aux VP
   b. NP → (D)N′
   c. N′ → N (S′)
   d. VP → V (NP)
   e. S′ → (C) S

These PS rules 'generate' or recognize the following phrase structure in (4) to be well-formed, while disallowing those in (5) from the possible phrase structures of English:

4.

I know the man who(m) you love.

5. a.

b.

c.

The PS rules in (3) also capture the recursive property of syntactic structures that is instantiated by the relative clause construction in (4), where the recursion of S (or a sentence) together with its internal phrasal categories is seen.

As it turns out, a theory incorporating PS rules of the type shown in (3) is too strong since it allows the positing of any kind of PS rules sanctioning phrase structures that are unlikely in human language. For example, PS rules (3b) and (3c) define an NP structure as one containing an N as its obligatory member. Similarly, PS rule (3d) stipulates V to be an obligatory member of a VP structure. These NP and VP structures are widely seen across languages. On the other hand, nothing prevents us from positing PS rules of the following type, which would sanction unlikely structures like those in (7):

6. a. NP → V S
   b. VP → D NP

7. a.

b.

Realization that NPs, VPs, and other phrasal categories of APs (adjectival phrases) and PPs (prepositional/postpositional phrases) all contain a core or 'head' constituent of N, V, A, and P, respectively, prompted the positing of X-bar schemata, as in (8), which would replace the individual PS rules generating these phrasal categories (Chomsky, 1970; Jackendoff, 1977). (This framework is known as 'X-bar' syntax because the original proposal was to use bars above the lexical categories to indicate the phrasal status of the relevant categories. The practice in the field has been to write $\overline{X}$ ($\overline{N}$ for example) as X′ (N′) for a typographic reason.)

8. a. XP = … X′
   b. X′ = … X

   where … is optional phrasal elements; X varies over N, V, A, and P; word order unspecified.

Unlike the traditional PS rules, X-bar schemata are meant to be universal constraints on possible phrase structures of human language and would predict that no language permits phrase structures of the type given in (7), where a phrasal category is not headed by a constituent of a similar category.

The X-bar schemata of the type in (8) handle endocentric phrasal structures, where a larger phrasal category is headed by a subcategory of the same kind; for example, NPs headed by an N′ and the latter by an N. However, they would not define the structures of clauses and sentences as these have been traditionally considered exocentric, where a higher structure is of different constituent type (e.g., S) from any of the immediately lower constituents (e.g., NP, Aux, and VP). Positing PS rules like (3a) and (3e) for clauses and sentences undermines the effort to constrain the theory sufficiently so as to bar arbitrary PS rules that make wrong predictions about possible phrase structures. Besides, permitting both endocentric and exocentric structures goes against Occam's razor. What has been proposed is a radical departure from the traditional conception about the structures of clauses and sentences, whereby a functional category representing inflectional features, I, has been recognized as the head of a clause, and the complementizer category C has been introduced as the head of a sentence. In other words, IP, the maximal projection of I, and CP, the maximal projection of C, have been proposed as the clausal and sentential structures, as in the following representations:

9.

10.

Besides the two functional (as opposed to lexical categories such as N and V) categories of I and C, D, for determiners, have been proposed as another functional category that heads a noun phrase. Now the traditional NPs have been reanalyzed as DPs of the following structures:

11.

Notice that IP, CP, and DP are all endocentric structures, unifying them with other endocentric structures of VP, AP, and PP. This generalization over various types of phrase structures, however, has been achieved at the great cost of losing the fundamental understanding of the notion of endocentricity. Endocentric structures are defined as those that function similarly to one of their constituents, namely to their heads. Endocentric structures result from structural elaborations of head constituents such that functioning endocentric structures are replaceable by head constituents without affecting the relevant functions. For example, the VP *slept three hours in the office* in *John slept three hours in the office* can be replaced by the head *slept* without affecting the grammaticality of the sentence as *John slept* indicates. Similarly the NP constituent *these very expensive books* can be replaced by the head *books* without affecting the well-formed NP structure. In the case of the proposed IP, CP, and DP, however, they are certainly not elaborations of I, C, and D in a similar way VPs and APs are of their head V and A. Indeed IPs, CPs, and DPs do not function like their heads, and certainly cannot be, respectively, replaced by I, C, and D without affecting the grammaticality of the resulting structures. In other words, IP, CP, and DP are not functionally endocentric at all. This is easy to see if we consider the function of NPs, now reanalyzed as DPs. The central function of NPs is reference, that is, a speech act of pointing out and distinguishing an entity in the universe of discourse from other similar entities. This function of NPs is based on the entity-denotation property of an N head, not that of a determiner modifying the N head.

In functional terms exocentric structures for clauses and sentences make good sense. While VPs and NPs, respectively, have a predication and referential function whether they simply consist of a head V or N, or they have elaborate endocentric structures with modifying elements, clauses, and sentences perform different functions from either VPs or NPs. Clauses have the function of materializing the predication function of a VP by ascribing the relational property denoted by a VP to the referent of a subject NP. Sentences, on the other hand, perform speech acts of various sorts. A declarative sentence, for example, asserts the truth of the predication made by a clause. These properties of clauses and sentences distinguish them sharply from nominalizations, whose function is to denote entity-concepts just like nouns (see Section Structure, Use, and Form).

The purging of exocentric structures from linguistic theory seems premature. For one thing, exocentric structures are seen elsewhere in grammar. Compound words show both hierarchical internal structures and the headedness, as well as endocentric categorical patterns similar to phrasal structures. There are, however, many compounds in various languages that are exocentric in both semantic and structural terms. Japanese deverbal noun *nobori* 'climbing,' for example, is a noun distinguishing itself from the members of the verbal noun class. Verbal nouns such as *benkyoo* 'studying' and *ryokoo* 'travel' allow light-verb constructions supported by the verb *suru* 'do,' as *benkyoo*(=*o*) *suru* (studying (=ACC) do) 'do studying,' but nouns, including deverbals like *nobori* 'climbing,' do not permit light-verb constructions. When *nobori* is compounded with the noun *yama* 'mountain' as in *yama-nobori* 'mountain climbing,' we obtain an exocentric structure as in (12), where the entire word is a verbal noun, which allows the light-verb construction *yama-nobori* (=*o*) *suru* 'do mountain-climbing.'

12.

Chinese and Thai have both right-headed and left-headed N–V compounds. In addition they both have exocentric V–V compounds whose overall structures are N. For example, Chinese *hǎo-huài* (good–bad) 'quality,' *dà-xiǎo* (big–small) 'size,' *cháng-duǎn* (long–short) 'length,' *lěng-rè* (cold–hot) 'temperature'; Thai *phim-đìit* (to type-to tap on) 'typewriter,' *kan-chon* (to prevent-to collide) 'buffer,' *kam-phân* (to grasp-to mold) 'fist.'

Observations that words forming a sentence organize themselves into hierarchically structured constituents underlie the notion of phrasal categories such as NPs, VPs, and PPs that PS rules or X-bar schema are meant to define. However, whether or not these phrasal categories are universal has been a contentious issue. Informed of free word-order languages like Japanese and many Australian aboriginal languages, Hale (1983) proposed what is known as the configurational parameter dividing the languages of the world into configurational (e.g., English) and non-configurational languages (e.g., Japanese) with the assumption that while the former type of languages have phrasal categories such as NP and VP, the latter may not. The extremely 'flat' Pamangyngian language of Australia Kalkatungu is reported to allow reordering of sentence elements in any manner even dispersing semantically related words at a great distance as in the following sentence, where *japacara-tu* 'clever-ERG' is placed far away from what it semantically modifies, namely *kuḷa-ji* 'father-ERG' (Blake, 1979):

13. Ṇa-ci kuḷa-ji ḷaji ṯuar-Ø malṯa j apacara-ṯu.
    1SG-DAT father-ERG kill snake-ABS mob-ABS clever-ERG
    'My clever father killed the snakes.'

The pairing of the semantic head and its modifier is made possible thanks to the case markers (glossed as ABS and ERG in the example above) that identify semantically related words. What is of interest here is that these discontinuous 'constituents' call into question some of the syntactic tests identifying constituents such as the ones below that are standardly introduced in introductory syntax textbooks:

14. Some proposed constituency tests
    a. Only a constituent can answer a question, while retaining the meaning of the original sentence.
    b. Only constituents can be substituted with pro-forms like *it*, *that*, *them*, *then*, *there*, *do that*, *that way*, ….
    c. Only constituents (of the same type) can be coordinated using conjunction words like *and*, *or*, and *but*.

Test (14b) tells us that while the underlined part of (15a) is a constituent, the underlined portion of (15b) is not. Similarly (14c) predicts that while the underlined parts of (16a) are constituents, the underlined portions of (16b) are not:

15. a. Jane married *the man whom she loved*, although **he** was poor.
    b. *Jane married *the man* whom she loved, although **he** whom Mary also loved was poor.
16. a. *The trip to London* and *the party in East London* were both enjoyable.
    b. John gave *a book to Mary* and Bill gave *a CD to Janet*. **The book to Mary* and *the CD to Janet* were both expensive.

If these tests were valid, we would expect the discontinuous elements *kuḷa-ji* 'father-ERG' and *japacara-tu* 'clever-ERG' in the Kalkatungu example in (13) to fail them. However, this does not appear to be the case; (13) may be following by the following sentence, where the pronominal form *li-ji* 'he-ERG' substitutes not just *kuḷa-ji* 'father-ERG' but the entire discontinuous elements *kuḷa-ji* 'father-ERG' … *japacara-tu* 'clever-ERG,' since (17) is likely to mean "The clever father cooked the meat":

17. Ḷi-ji ṯuji-ṇa ati.
    he-ERG cook-PAST meat
    'He cooked the meat.'

Moreover, a nominal phrase and a noncontiguous modifier together may be conjoined with another nominal phrase, as in the following example, where the modifier *japacara-ṯu* 'clever-ERG' can be associated with either *na-ci kuḷa-ji* 'my father-ERG' or *marapai-ṯu* 'woman-ERG' – notice that (18) does not mean "my father and the woman, who are clever …" (Van Valin, 2001):

18. Ṇa-ci kuḷa-ji marapai-ṯu-jama ḷaji ṯuar-Ø malṯa
    1SG-DAT father-ERG woman-ERG-and kill snake-ABS mob-ABS
    japacara-ṯu.
    clever-ERG
    'My clever father and the woman killed the snakes.'
    'My father and the clever woman killed the snakes.'

These possibilities in Kalkatungu, where discontinuous 'constitutes' of the above type abound, suggest that some of the constituency tests are really for semantically connected units rather than syntactic or phonological groupings. It so happens that in those languages used to demonstrate the notion of constituency semantically related elements tend to be grouped together phonologically, as in English.

Grammatical Relations

The theoretical status of grammatical relations or functions such as subject, object, and indirect object, and the question of whether or not they – the subject in particular – are universal relational categories have also been contentious perennial issues in syntax. While descriptive grammars in general tend to continue the traditional definition of subject as the NP representing an agent, Chomskyan generative grammar made a radical departure from this tradition in defining grammatical relations subject and object in structural terms, in part due to the fact that the traditional equation of agent = subject does not work in many cases including the subject of a passive sentence. The earlier version of the structural definitions holds subject to be an NP immediately dominated by S and object to be an NP immediately dominated by VP (Chomsky, 1965). Structurally-based definitions like these and those based on the more recent X-bar version of PS rules, where subject is defined as a Specifier of XP, however, assume that all languages having these grammatical relations have configurational structures similar to English (cf the earlier discussion on non-configurational languages).

While the strict Chomskyan generative tradition holds grammatical relations to be derived notions definable in structural terms, other approaches such as Relational Grammar (Perlmutter, 1983) and Lexical Functional Grammar (Bresnan, 2001) regard them to be universal theoretical primitives necessary in capturing universal properties of syntactic rules (e.g., passivization is defined as a relation-changing rule of turning object into subject) and constraints on the distribution of grammatical relations (e.g., a single clause may have at most a single subject, this constraint being responsible for disallowing a passive sentence from having two subjects).

The position that grammatical relations are language universals has posed a serious challenge in identifying subject and other grammatical relations in two groups of languages, namely so-called ergative languages, where what, on morphological grounds, appear to be the subject of a transitive sentence corresponds to a direct object of languages like English, and Western Malayo-Polynesian languages, where what appears to be a subject is not always aligned with an agentive NP even in what seem to be basic structures. The problem of identifying grammatical relations in different types of language even prompted a checklist approach, such as the one proposed by Keenan (1976), which lays out a set of subject properties that would help us identify a subject in any given language.

Much more empirically-minded typologists adopt a phenomenon-driven approach to grammatical relations, which recognizes grammatical relations only insofar as a phenomenon demands them (Dryer, 1979; Haspelmath, 2007). Whether a language possesses the grammatical relation subject, for example, can be determined on the basis of whether or not it displays a phenomenon that requires a grouping of argument types S (the argument of an intransitive sentence) and A (the agentive argument of a transitive sentence) to the exclusion of P (the patientive argument of a transitive sentence), since the S/A grouping is what the notion of subject represents in English and other European languages, in which the term subject has been invented. The following examples show the syntactic grouping of S and A arguments with regard to the distribution of pronominal case forms and the agreement pattern. The P argument is distinguished from these in case form (*her* as opposed to *she*) and in not triggering agreement:

19. a. She runs all the time. (S in 'she' form and agrees with the verb)
    b. She scolds them all the time. (A in 'she' form and agrees with the verb)

The phenomenon-driven approach to grammatical relations reveals that many of the so-called ergative languages involve subject (which groups S and A) and object (for P) relations as well as some other relations, which may be termed 'absolutive' (which groups S and P) and 'ergative' (for A) relations. In the following Warlbiri examples, agreement (or clitic placement) is controlled by the subject/object relations. The first person subjects (S and A) trigger *-ṇ* marking in the verb (see (20a) and (20c), whereas the first person object (P) triggers *-tju* marking (see (20b)). Thus, there is a clear-cut subject/object opposition in this language. Case forms, however, are controlled by a different set of relations. The absolutive relation (a grouping of S and P) demands the *ɲatju* form for the first person pronoun, as in (20a) and ((20b). On the other hand, the A argument holding the ergative relation appears in the ergative-marked *ɲatju-luḷu* form (20c):

20. Warlpiri (Australia; Hale, 1976)
    a. ɲatju ka-ṇa puḷa-mi
       1SG.ABS PRES-1SG shout-NONPAST
       'I am shouting/I shout.'
    b. ɲjuntu-luḷu ka-npa-tju ɲatju njanji
       2SG-ERG PRES-2SG-1SG 1SG.ABS see-NONPAST
       'You see me.'
    c. ɲatju-luḷu ka-ṇa-ɲku njuntu njanji
       1SG-ERG PRES-1SG-2SG 2SG.ABS see-NONPAST
       'I see you.'

Somewhat similar pattern emerges among Western Malayo-Polynesian languages, in which there are phenomena calling for both the subject relation (defined as a union of S and A, as above) and a distinct topic relation marked specially in some of these languages, as the *ang*-marking in Tagalog and the *'o*-marking in the Tsou language of Taiwan. Sasak, spoken in the Lombok Island in eastern Indonesia, presents one of the clearest cases of a language requiring both subject and topic relations. Sasak, like most Austronesian languages in Indonesia, has a two-way focus system, a remnant of the proto-Austronesian four-way focus system (see below), whereby transitive clauses can be coded either in the Actor-focus (AF) construction, where the A argument is aligned with the topic relation, or in the Patient-focus (PF) construction, where the P argument is the topic, as in (21a) and (21b):

21. Sasak (Puyung meno-mené dialect; Shibatani, 2008)
    a. Ali mu = *n* empuk aku. (AF construction)
       Ali PAST = 3 hit I
       'Ali hit me.'
    b. Aku mu = *n* empuk siq Ali. (PF construction)
       I PAST = 3 hit by Ali
       'Ali hit me.'
    c. Aku mu = *k* te-empuk siq Ali. (Passive)
       I PAST = 1 PASS-hit by Ali
       'I was hit by Ali.'
    d. Inaq mu = *n* lalo jok peken (Intransitive)
       mother PAST = 3 go to market
       'Mother went to the market.'

Cliticization operates according to the subject relation since S in (21d), the derived S of passive sentence (21c), and As in (21a.b) call for the cliticization of appropriate form, *-n* for a third person singular subject (21a.b.d) and *-k* for a first person singular subject (21c).

The topic in Sasak is not marked specially but appears sentence initially. Notice that PF constructions and passive constructions are two distinct constructions (cf (21b) and (21c)); PF constructions have the alignment patterns of A = SUB = Non-Topic and P = OBJ = Topic, whereas passives align P with subject as well as with topic, as P = SUB = Topic. There are several phenomena in which topics play a crucial role, including the controlling of a gap in coordinate constructions of the following type. Notice that in (22b) 'Ali' is an object

but it functions as the 'antecedent' of the gap in the second clause, while the subject 'Siti,' which triggers cliticization (see (21b)), does not:

22. Ganti meno-mené Sasak (author's field notes)
    a. Siti empuk Ali, terus Ø pelai=n (Ø =Siti)
       Siti hit Ali then run=3
       'Siti hit Ali, and ran away.'
       (AF: 'Siti'=A=SUB=TOP)
    b. Ali empuk=en siq Siti, terus Ø pelai=n (Ø =Ali, *Siti)
       Ali hit-3 by Siti then run=3
       'Siti hit Ali, and (Ali) ran away.'
       (PF: 'Ali'=P=OBJ=TOP)
    c. Ali te-empuk siq Siti, terus Ø pelai=n (Ø =Ali, *Siti)
       Ali PASS-hit by Siti then run-3
       'Ali was hit by Siti, and ran away.'
       (Pass: 'Ali'=P=SUB=TOP)

Besides these phenomena that specifically call for the subject and the topic relation, there are those that require the alignment of SUB = TOP such as the controlling of the gap in the '*try*-constructions' (Ali nyobaq [Ø ngiduk Siti] 'Ali tried to kiss Siti').

Just as the properties of subjects differ across different languages, topic properties also differ from one language to another. While topics of Western Malayo-Polynesian languages are involved in various syntactic phenomena, resembling subjects in European languages to a varying extent, topics in Asian languages such as Japanese and Korean are less relevant to those phenomena controlled by subjects in these and other languages.

Although the above survey shows that many languages, including controversial ergative and Western Malayo-Polynesian languages, may have a subject, the universality of this relational category must still be empirically established. Toward this end, future descriptive grammars must each demonstrate the need for positing grammatical relations of various sorts by the kind of procedure described above.

Structure, Use, and Form

Both traditional and modern grammarians have not been very successful in distinguishing structures (linguistic units or constructions), their uses (functions), and forms that may vary according to use and function. For example, 'possessor' expressions such as *my/mine*, *your/yours*, *his/his*, and so on have traditionally been analyzed as belonging to separate parts of speech (i.e., as distinct structures) depending on their use. They are recognized as 'possessive pronouns' ('posesivos pronombres' in Spanish) when they function as the head of a noun phrase, as in (23a), and as 'possessive adjectives' ('posesivos adjetivos') when they modify, as in (23b):

23. a. [Mine/yours/his/my younger brother's] are those piled up on the table over there.
    b. [my/your/his/my younger brother's] books.

Besides the problem of identifying forms such as *my younger brother's* either as pronouns or adjectives – they are not words – this kind of analysis confuses structures and their use. While many structures need to undergo category change when they play different functions, some do not. In particular, nouns in many languages can modify another noun without changing their category from noun to adjective. For example, the English noun *cotton* typically heads a noun phrase, as in (24a), where it realizes a referential function of the NP. A noun may, in addition, function as a modifier of another noun as in (24b):

24. a. $[[\text{Cotton}]_N]_{NP}$ is a useful commodity. (NP-use of a noun)
    b. $[\text{a } [[\text{cotton}]_N\ [\text{shirt}]_N]_{N'}]_{NP}$ (Modification-use of a noun)

That nouns do not become adjectives in their modification function is seen from the fact that they continue to be modified by an adjective, not an adverb that adjectives call for, as in the expressions *an Egyptian cotton shirt*, *developmental psychology students*, and so on. Interestingly so-called relative clauses also have the two types of use exemplified above:

25. a. You should marry [who you love].
    b. You should marry the man [who you love].

Capturing the parallelism between the two uses across these constructions requires proper understandings of the 'possessive' forms and so-called relative clauses so that we can describe these patterns in an analogous form as we do for the two uses of nouns seen in (24); that is, where structure X is used as the head of an NP as 'an NP-use of X,' and where X is used as a modifier as 'a modification-use of X.' Some measure of effort in capturing the relationship between the bracketed portions in (25a) and (25b) is seen in the typological literature, where forms like the one in (25a) are considered a type of relative clause, namely 'headless relative clauses' (Keenan, 1985; Kuroda, 1976; Andrews, 2007). A major problem with this widely accepted approach is that it is based on a wrong-headed perspective similar to characterizing the relevant forms in (23a) as 'headless possessive adjectives' and those in (24a) as 'headless modifying nouns.' Terms like 'headless relatives' and the alternative 'free relatives' are oxymora – things cannot be 'relatives' when they have nothing to relate to.

Indeed, the relevant form in (25a) does not modify, while the function of true relative clauses is to modify a head noun as in (25b). Instead of modifying, the form in (25a) and its equivalents in other languages actually denote thing-like concepts (e.g., those people evoked and characterized by the structure [who you love] in (25a)). That is, the form in question has a nominal property of denoting thing-like concepts. A more promising line of analysis for the patterns exemplified by (25a) and (25b) recognizes processes and structures termed 'grammatical nominalizations' (Shibatani, 2009; Yap et al., 2011). Unlike lexical nominalizations, which are nouns registered in the lexicon, grammatical nominalizations are not nouns – they typically have structures larger than words – and are created for the nonce.

Grammatical nominalization is a metonymic process that yields nominalized structures associated with various entity-denotations such as events, facts, propositions, places, reasons, times, and participants associated with the events evoked by the nominalized structures. Languages in general make

a formal distinction between 'event nominalizations' and 'argument/participant nominalizations,' as in the following examples, where these may differ in terms of marking and whether the structure contains a missing argument or not:

26. a. I know [that you love that man]. (Event nominalization)
    b. Marry [who you love __] (Argument nominalization)

The gap in an argument nominalization indicates the grammatical role that the evoked entity is to be understood to play. In (26b) the 'object nominalization' denotes a person that the addressee loves. While many languages (e.g., Chinese, Japanese, and Korean) have no marking other than the position of a gap in indicating the role of the argument denoted by an argument nominalization, many languages have special markers that indicate such roles (as well as some other information). The basic functions of the so-called focus markers in Austronesian languages are to mark the grammatical roles in argument nominalizations. The Actor-focus (AF), Patient-focus (PF), Locative-focus (LF), and Circumstantial-focus (CF) markers, respectively, indicate that the denoted argument is agentive, patientive, locative, and benefactive/instrumental, as in the following Mayrinax Atayal (Taiwan) examples:

27. Mayrinax Atayal argument nominalizations (based on Huang, 1995)
    a. Actor nominalization
    ßaq-un = mu ku? [m<in>aniq cu? goqiluh] ka? haca?
    know-PF = 1SG.GEN NOM.REF AF<PERF>eat ACC banana LINK that
    'I know that one who ate banana.'
    b. Patient nominalization
    ßaq-un = mu ku? [t<in>uting = si hisa]
    know-PF = 1SG.GEN NOM.REF <PF.PERF>beat = 2SG yesterday
    'I know the one you beat yesterday.'
    c. Locative nominalization
    ɣaɣhapuyan ku? [naniq-an cu? ßuŋa? nku? ?ulaqi?]
    kitchen NOM.REF eat-LF ACC.NONREF yam GEN.REF child
    'The kitchen is where the child eats yam.'
    d. Circumstantial (benefactive/instrumental) nominalization
    ini = mu s?wa? = i ku? [si = ghahapuy nku? kanairil]
    NEG = 1SG like = LF NOM.REF CF = cook GEN.REF woman
    'I don't like the one for whom the woman cooks.'

So-called German relative pronouns *der*, *den*, *dem*, *dessen* are in fact nominalizers of the same sort as the Austronesian focus markers, respectively, marking subject, object, indirect object, and genitive nominalizations. English nominalization markers include *who*, *whom*, *whose*, *why*, and *where*, which indicate the grammatical roles, and *which* and *what* contrasting with *who/whom* in marking inanimate denotations.

Now, parallel to the usage pattern of nouns in (24), event nominalizations have two major uses, as below:

28. a. I know [that you love that man]. (NP-use)
    b. I know the fact [that you love that man]. (Modification-use)

In (28a) an event nominalization heads an NP functioning as the object of the verb *know*, while in (28b) the same form modifies the head noun *fact*. This is precisely the way the pattern in (25) should be analyzed. Namely (25a) instantiates an NP-use of an argument nominalization, and (25b) initiates a modification-use of the same argument nominalization. What have been considered relative clauses are nothing but a modification-use of argument nominalizations. See the following Mayrinax Atayal examples, where the Actor and Patient nominalizations in (27) are used as a modifier together with the linker.

29. a. Modification-use of an Actor nominalization
    kanairil ka? [m<in>aniq cu? goqiluh]
    woman LINK AF-<PERF>eat ACC banana
    'woman who ate a banana'
    b. Modification-use of a Patient nominalization
    ?uliaqi? ka? [t<in>uting = si hisa]
    boy LINK <PF.PERF>beat = 2SG yesterday
    'boy whom you beat yesterday.'

Besides the ones based on clausal units as seen above, various structures can be nominalized grammatically. What we observed earlier in (23) exemplify nominalizations of pronouns and noun phrases. *Mine*, *my younger brother's*, and so on evoke denotations closely associated with the referents of the pronoun *I* and the noun phrase *my younger brother* – the most immediately evoked denotations being things that are possessed by these referents. Then, (23a) exemplifies an NP-use of nominal-based nominalizations, and (23b) a modification-use of the same N-based nominalizations. Notice that forms of the N-based nominalizations differ for some (*mine* vs *my*) according to their use/function, while some (*his* vs *his*) remain the same. It is often the case that the NP-use of nominalization calls for a special marker indicating its referential function as in the case of *one*-marking seen in nominalized prepositional phrases (*one[on the table]*) and nominalized adjectival phrases (*one [highly expensive and valuable]*). Notice that *one*-marking does not occur in the modification-use (*the book [on the table]*, *the book [highly expensive and valuable]*.) This is indeed what we observe between the two uses of argument nominalizations, as below (The use of numerals as

markers of the NP-use of nominalizations is also seen in the Indo-Aryan language Sinhala.):

30. a. I know the one [who __ came yesterday]. (NP-use)
    I know the man [who __ came yesterday]. (Modification-use)
31. b. Show me the one [which you bought __ yesterday]. (NP-use)
    Show me the book [which you bought __ yesterday]. (Modification-use)

The marginal NP-use of argument nominalizations without *one*-marking seen in Modern English above (see (26b)) is a remnant of a much more widespread use of these argument nominalizations as an NP-head without *one*-marker in an earlier form of English. The development of *one*-marking for the NP-use of argument nominalizations since the time of Middle English parallels the rise of *no*-marking of the NP-use of grammatical nominalizations in Japanese in the beginning of the sixteenth century. These markers of the NP-use of nominalizations, such as English *one*, Japanese *no*, and Korean *kes*, must be distinguished from nominalizing particles like Mandarin Chinese *de* and Nepali *ko*, which occur in both NP and modification functions. Compare the Korean and Mandarin Chinese examples below:

32. Korean argument nominalizations
    a. Na = nun [apeci = ka cwu-n] = *kes* = ul ilk-ko-iss-ta. (NP-use)
       I = TOP father = NOM give-NMLZR = NM = ACC read–CON–be-IND
       'I am reading what father gave (me)'
    b. [apeci = ka cwu-n] chaek (Modification-use)
       father = NOM give = NMLZR book
       '(the) book which father gave me'
33. Korean N-based nominalizations
    a. [emeni = uy] = *kes* = un ku chaek i-ta. (NP-use)
       mother = NMLZR = NM = TOP that book COP = IND
       'Mother's is that book.'
    b. [emeni = uy] chaek (Modification-use)
       mother = NMLZR book
       'mother's book'
34. Mandarin Chinese argument nominalizations
    a. Nǐ méi yǒu [wǒ xǐhuān = *de*] (NP-use)
       you not have I like = NMLZR
       'You don't have what I like.'
    b. [wǒ xǐhuān = *de*] yīfu (Modification-use)
       I like = NMLZ clothes
       '(the) clothes that I like'
35. Mandarin Chinese N-based nominalizations
    a. Zhèi běn shū shì [wǒ = *de*]. (NP-use)
       this CLF book is I=NMLZR
       'This book is mine.'
    b. [wǒ = *de*] shū (Modification-use)
       I=NMLZR book
       'my book'

The fact that some of these two types of nominalization markers are used for both argument nominalizations and N-based nominalizations supports the analysis of the latter (*mine/yours/my younger brother's*, and so on) as nominalizations (see also Matisoff, 1972).

Reanalyzing so-called relative clauses and so-called complement clauses such as (26a) as nominalizations has profound implications to the past traditional and generative, as well as typological studies of these constructions. Firstly, contrary to the traditional label relative 'clauses,' nominalizations are not clauses even if their internal structures look clausal with verbal syntax (see e.g., (28a)). Once various grammatical units are nominalized, they behave like nouns. In particular, nominalizations denote entity concepts rather than predicate, which is the function of clauses, and neither do they assert like (declarative) sentences. The nominalization *that you love that man* in (28a), for example, does not predicate or assert; instead it denotes a fact. The impression that this expression predicates is due to the presupposition that it is associated with. The same presupposition property obtains with so-called relative clauses.

The nominalization analysis also casts doubt on both traditional and more recent analyses of relative clauses within the Chomskyan generative framework, which assume that there is recursion/embedding of S or IP/CP, that is, either sentences or clauses (see (4)). The nominalization analysis claims that sentences and clauses cannot be embedded unless they are first nominalized. This is a desirable consequence. As discussed in the Section Phrase-Structure Rules, Phrasal Categories, and Constituency, constraining the grammar/theory has been one of the prime concerns of generative syntacticians. The current

theory is still very powerful, indeed too strong, since it allows embedding of S/IP/CP within a phrase smaller in structure than these, namely NP (in the case of N complements and relative clauses) and VP (for V complements). The nominalization analysis entails a much more constrained theory of syntax allowing recursion/embedding of only elements equivalent to or smaller than the hosting structures.

Finally, the nominalization analysis of relative clauses undermines the fundamental assumption underling the notion of NP-accessibility developed in one of the most influential typological studies of relative clauses by Keenan and Comrie (1977), where it is assumed that there are relativization processes that target NPs holding specific grammatical relations such as subject, direct object, and indirect object. This has yielded a typological classification of relative clauses – and the languages possessing them – on the basis of whether relativization is accessible/applicable only to subjects, to subjects and direct objects, to subjects, direct objects, and indirect objects, and so on. Within the nominalization analysis, relative clause formation is simply juxtaposing of a head noun and an argument nominalization, and no notion of grammatical relations is involved in the relativization process per se. Argument nominalizations are characterizable as subject nominalization, object nominalization, and so on, but this is totally independent from the process of relativization.

Syntax–Phonology Interface

Abstract

The bulk of evidence concerning the syntax–phonology interface shows an influence of syntax on phonology. The domain structure for sentence-level phonological and phonetic phenomena, which forms part of the surface phonological representation (PR) of the sentence, is defined through an interaction of two types of constraints: syntax–prosodic structure interface constraints, which call for certain properties of the surface syntactic representation of the sentence (PF) to be reflected in domain structure in PR, and prosodic structure markedness constraints, which call for the surface prosodic structure to display patterns of unmarked prosodic structure. The effects of prosodic markedness constraints argue against direct access theories, which see phonological phenomena as defined directly on the surface syntax. Distinguishing PF and PR raises the question whether PF is input to the phonological component, with PR the output, as in standard models of generative grammar, or whether there may be mutual influence. Current models of grammar would countenance effects in the other direction, with the possibility of phonological principles constraining the range of acceptable surface syntactic representations, and research is beginning to explore this area.

The bulk of evidence concerning the syntax–phonology interface shows an influence of syntax on phonology. The domain structure for sentence-level phonological and phonetic phenomena, which forms part of the surface phonological representation (PR) of the sentence, is defined through an interaction of two types of constraints: *syntax–prosodic structure interface constraints*, which call for certain properties of the surface syntactic representation of the sentence (PF) to be reflected in domain structure in PR, and *prosodic structure markedness constraints*, which call for the surface prosodic structure to display patterns of unmarked prosodic structure. The effects of prosodic markedness constraints argue against direct access theories, which see phonological phenomena as defined directly on the surface syntax. Distinguishing PF and PR raises the question whether PF is input to the phonological component, with PR the output, as in standard models of generative grammar, or whether there may be mutual influence. Current models of grammar would countenance effects in the other direction, with the possibility of phonological principles constraining the range of acceptable surface syntactic representations, and research is beginning to explore this area.

An individual word, pronounced in isolation, will have a characteristic pronunciation. Yet the pronunciation of a sentence, made up of a sequence of words, is not merely a stringing together of these individual pronunciations. The pronunciation of a sentence, i.e., its phonetic realization, is a function of the surface phonological representation of the sentence. Standard models of the organization of a grammar hold that this phonological representation interfaces with the surface syntactic representation of the sentence, the latter being made up of the sequence of the underlying phonological representations of the words and morphemes that are actually pronounced, and their organization into a syntactic word and phrase structure. This organization of the grammar permits in principle that the syntactic representation of a sentence may influence its phonological representation, and therefore allows an explanation for why sentence phonology is not simply the phonology of the individual words of the sentence strung together. Consider, for example, the sentence pairs *No people will go* vs. *No, people will go* and *People will go happily* vs. *People will go, happily*. In both cases, commas indicate a difference in syntactic structure within the pairs. That syntactic structure difference is reflected in a difference in pronunciation, specifically here in a difference in intonation. Effects like these of syntax on phonology have been studied most commonly, in part because earlier models of generative grammar sanctioned only effects in this direction. It is also possible that effects might go in the opposite direction, with phonological principles constraining the range of acceptable syntactic representations at the interface; some recent research explores this question.

Two major lines of thinking on the influence of syntax on phonology can be distinguished. The *prosodic structure hypothesis* holds that the phonological representation of a sentence is organized into a prosodic constituent structure which is independent of, but related to, the surface syntactic structure of a sentence (Selkirk, 1986, 1995; Nespor and Vogel, 1986; Truckenbrodt, 1999). It claims, moreover, that the syntax of a sentence can impinge directly only on this prosodic structure, namely on the organization into phonological words or phrases, and on the distribution of prosodic heads (or stresses). Other apparent effects of syntax on phonology, e.g., the choice of segmental variants or the placement of certain phrasal tones, are claimed to be indirect, mediated by the prosodic structure organization. And since the phonetic interpretation of a sentence is based on surface phonological representation, it follows that there are no direct effects of syntax on phonetic form. If the prosodic structure hypothesis embodies the correct theory of the domain structure for sentence phonology, then the theory of grammar must distinguish between the surface phonological representation of a sentence (PR), which would include this prosodic structure, and its surface syntactic representation (PF). The *direct access hypothesis* (Kaisse, 1985; Odden, 1995), by contrast, holds that phenomena of sentence phonology and phonetics may be defined directly from the surface syntactic word and phrase structure. It does not require a theory of grammar that distinguishes the surface syntactic representation of a sentence crucially from its surface

phonological representation, at least in its hierarchical structure. Evidence appears to favor the prosodic structure hypothesis.

The Prosodic Structure Hypothesis

A prosodic structure is a well-formed labeled bracketing or tree. The constituents of prosodic structure belong to distinct prosodic categories, arranged in a *prosodic hierarchy*.

(1) The Prosodic Hierarchy:
Utterance (Utt)
Intonational Phrase (IP)
Major Phonological Phrase (MaP)
Minor Phonological Phrase (MiP)
Prosodic Word (PWd)
Foot
Syllable

In the unmarked case, it is claimed, prosodic structure is *strictly layered*, in the sense that a constituent of a higher level in the hierarchy immediately dominates only constituents of the next level down in the hierarchy. In addition, within a prosodic constituent, in the unmarked case, one of the daughter constituents constitutes the *prosodic head*, the locus of prominence or stress. Compelling support for the claim that the domain structure of sentence phonology and phonetics has the formal properties of such a structure comes from evidence of *domain convergence* and *domain layering* within individual languages. Yet a direct access approach could potentially model these effects. Crucial support for the prosodic structure hypothesis comes from the fact that the constraints which define the hierarchical phonological domain structure are heterogeneous in type, including *prosodic structure markedness constraints* which are properly phonological in character, appealing only to properties of surface phonological representation, and *syntax-prosodic structure interface constraints*, which call for features of the syntactic representation to be reflected in phonological representation. Effects of prosodic markedness constraints show that the domain structure of surface phonology is not strictly determined by the syntax, only influenced by it.

Domain Convergence

In English declarative sentences, the right edge of a major phrase (MaP) in prosodic structure is marked by the presence of a low tone. In (1a,b) a L- marks the low target tone found on the final syllable of a MaP.

(2) (a) (No^{L-}) (animals are allowed^{L-}) =
No, animals are allowed.
[ɨænɨmlz]
(b) (No animals are allowed^{L-}) =
No animals are allowed.
[ænɨmlz]

We also see a segmental reflex of that same MaP organization: a glottal stop appears as the onset of the first syllable of *animals*, [ɨænɨmlz], in (2a), where it is phrase-initial, but not in (2b). This glottalization effect is arguably phonetic in character (Dilley and Shattuck-Hufnagel, 1996). In (3a,b) we see an additional MaP effect: a contrast in the pronunciation of the function word *to*.

(3) (a) (They're allowed to graze there^{L-}) (by law^{L-}).
[tə]
(b) (They're allowed to^{L-}) (by law^{L-})
[tuw]

To appears in its stressless, vowel-reduced weak from [tə] in (3a), where it is medial within the MaP, but in its stressed, full vowel strong form [tuw] when it appears at the right edge of MaP in (3b) due to the ellipsis of the following verb phrase. In English, monosyllabic function words like *to* generally appear in strong form only at the right edge of MaP (or when they bear contrastive stress) (Selkirk, 1995). These three different phenomena which converge on major phrase in English together show that both edges of these constituents are simultaneously relevant to defining phonetic and phonological phenomena.

In Bengali sentence phonology (Hayes and Lahiri, 1991), MaP is marked at its right edge by a H- tone. The left edge of MaP is the locus of further phenomena: the word that is leftmost in a MaP is the head of that phrase, and a Low pitch accent, L*, is located on the initial syllable of this stressed word:

(4) (ʃæ^{L*}moli^{H-}) (ra^{L*}m-er bari^{H-}) (ɖ^{h}u^{L*}ketʃ^{h}il^{H-})$^{L°}$
Shamoli Ram's house entered
Shamoli entered Ram's house.

In addition, there are segmental assimilation phenomena which apply optionally both within and between words. These assimilations operate across the span of the MaP, but are blocked if the sequence of segments belongs to different phrases:

(5) (ɔ^{L*}mor^{H-}) (tʃa^{L*}dor^{H-}) (ta^{L*}ra-ke^{H-}) (díe^{L*}tʃ^{h}e^{H-})$^{L°}$
[r] [tʃ] [r] [t]
Amor scarf Tara–to gave
Amor gave the scarf to Tara.
(6) (ɔ^{L*}mor tʃador tara-ke^{H-}) (díe^{L*}tʃ^{h}e^{H-})$^{L°}$
[tʃtʃ] [tt]
Amor gave the scarf to Tara.

The faster pronunciation in (6) is organized into fewer MaP than in the more deliberate pronunciation of the same sentence in (5). This difference in domain organization is indicated both by the patterns of tone distribution and by the assimilation of /r/. This Bengali phrasal domain, then, shows right and left domain-edge phenomena, as well as phenomena defined on the prominent head of the domain and across the span of the domain.

Domain Layering

The edge of a clause in the syntax typically coincides with the edge of what prosodic structure theory calls the intonational phrase (IP), the prosodic constituent immediately superordinate to the MaP in the prosodic hierarchy. In English, a final rising tonal contour on the last syllable of word (notated$^{L\text{-}H°}$), sometimes referred to as the continuation rise, is taken to indicate the presence of the right edge of IP (Beckman and Pierrehumbert, 1986), indicated with curly braces.

(7) {(Since herds of grazing cows^{L-})
[hrdz]
(have been allowed in her meadow^{L-})$^{H\%}$}
[əv] [ɾ]
{(her flowers have all disappeared^{L-})}
[hɾ] [əv]

The right edge of an IP typically is accompanied by a short pause or a significant lengthening of the final syllable. In English (and other languages) the left edge of IP is, moreover, the site of phonetic strengthening effects that are potentially different in kind or in degree from those seen with the major phrase (Keating et al., 1998). For example, an underlying /h/ in English will typically fail to be pronounced if it is in an unstressed syllable (compare stressed *herds* to stressless *her* in the first clause), but at the beginning of an IP /h/ must necessarily be pronounced, even in a stressless syllable (compare stressless *her* in the second clause to stressless *her* in the first). By contrast, there is the possibility of absence of /h/ in the stressless *have* which is MaP-initial in the first clause. This difference in appearance of [h] provides further testimony of the difference in the two levels of domain structure.

In Japanese, a rise (LH) in pitch which is referred to as Initial Lowering is found at the left edge of a minor phrase (MiP) (Poser, 1984; Kubozono, 1993), indicated with angle brackets in (8b).

(8) (a) Yamaai-no yamagoya-no uraniwa-no umagoya-ni kabi-ga hae^{H*}-ta
[[[[mountain village-GEN] hut-GEN] backyard-GEN] barn-LOC] [mold-NOM] [grow-PAST]
The barn in the backyard of a hut in a mountain village grew moldy.
(b) $^{L}<^{H}$ Yamaai-no yamagoya-no$>^{L}$ $<^{H}$ uraniwa-no umagoya-ni$>\uparrow^{L}<^{H}$ kabi-ga hae$^{H*}\downarrow$-ta$>)^{L}$

Sentence (8b) shows an organization into binary MiP. In (9b), by contrast, where all the words have a lexical accent, we see that there are as many instances of MiP, and hence of Initial Lowering, as there are of accents:

(9) (a) Yama^{H*} gata-no yama^{H*} dera-no one:^{H*} san-ga mayone:^{H*} zu-o ho:ba^{H*} tteiru-wa
[[[Yamagata-GEN] mountain temple-GEN] young-lady-NOM] [[mayonnaise-ACC] filling-her-mouth]
The young lady from a mountain temple in Yamagata was filling her mouth with mayonnaise.
(b) ($^{L}<^{H}$yama$^{H*}\downarrow$gata$>^{L}<^{H}$yama$^{H*}\downarrow$dera$>^{L}$ $<^{H}$one:$^{H*}\downarrow$san-ga$>\uparrow^{L}<^{H}$ mayone:$^{H*}\downarrow$zu-o$>^{L}<^{H}$ho:ba$^{H*}\downarrow$tteiruwa$>)^{L}$

The difference in patterns of minor phrasing seen in (8) and (9) are the result of prosodic markedness constraints, to be discussed below.

At the level of MaP, the level above MiP in the prosodic hierarchy, two tonal phenomena, are defined: catathesis (↓), and upward pitch reset (↑) (Poser, 1984; Pierrehumbert and Beckman, 1988). Catathesis is an accent-induced downstepping of the pitch range, while upward pitch reset returns the pitch range to a higher level. Only material within the same MaP undergoes catathesis. Upwards reset, seen in both (13) and (14), appears at the left edge of MaP. These examples, then, illustrate the basic strict layering of unmarked hierarchical prosodic structure: here a MaP is parsed into a sequence of MiP.

Nonsyntactic Determinants of Phonological and Phonetic Domain Structure

A direct access theory could model patterns of edge-sensitive phonetic and phonological phenomena as long as the edges were definable solely in syntactic terms. But demonstrably nonsyntactic factors in phonological domain organization, such as prosodic markedness constraints and speech rate, show that the influence of syntax is indirect.

The interaction of prosodic markedness constraints and interface constraints

In optimality theory (Prince and Smolensky, 1993), phonological markedness constraints call for some ideal phonological target output shape. Of particular importance to our topic, markedness constraints compete with a class of constraints called faithfulness constraints, which call for properties of the surface phonological representation to reflect, or be identical to, properties of a related grammatical representation. Syntax–phonology interface constraints can be understood as a variety of faithfulness constraint, one of the input–output variety, if surface syntactic representation (PF) and surface phonological representation (PR) are in an input–output relation, or one of an output–output variety, if the PF and PR relation are evaluated in parallel, not serially.

In the examples of Japanese minor phrasing cited in (8) and (9), prosodic markedness constraints complement the effects of syntax–phonology interface constraints, producing phrasing where it would not be called for by the syntax. A prosodic constraint calling for a MiP to be binary in its PWd composition, call it Binary MiP, results in the binary phrasing seen in (8). Another prosodic constraint, call it MiP Accent, calls for a MiP to contain at most one accent; it is responsible for the appearance of the nonbinary MiP in (14). In Japanese, MiP Accent takes precedence over Binary MiP, as in (9), a relation that can be expressed in the grammar of Japanese with an optimality-theoretic constraint ranking: MiP Accent ≫ Binary MiP.

The ideal binary shape for MiP, which appears in (8), fails to appear in sentences with somewhat different syntactic structures, showing that certain syntax–phonology interface constraints also outrank the Binary MiP markedness constraint in the grammar of Japanese. The simple three word subject–object verb sentence (10) divides into two major phrases (MaP) at the break between subject and object, with the result that the subject consists of a nonbinary minor phrase (MiP), in violation of Binary MiP:

(10) (a) Inayama-ga yuujin-o yonda
[[Inayama-NOM] [[friend-ACC] call-PST]]
Mr Inayama called his friend.
(b) ($^{L}<^{H}$Inayama-ga$>\uparrow$($^{L}<^{H}$yuujin-o yonda$>)^{L}$

The MaP break here is imposed by a syntax–phonology interface constraint expressible as the alignment constraint (Selkirk and Tateishi, 1988, 1991):

(11) Align-L (XP, MaP)
The left edge of a maximal projection in syntactic representation (PF) corresponds to the left edge of a major phrase in surface phonological representation (PR).

The noun phrase (12), which consists of an accentless Adjective–Adjective–Noun sequence, consists of a single MaP (as shown by lack of internal upward pitch range reset), but nonetheless shows a MiP break between the two adjectives, leaving the first MiP nonbinary.

(12) (a) Amai akai ame-ga
[sweet [red [candies]]]
(b) $({}^{L}<{}^{H}\text{amai}>{}^{L}<{}^{H}\text{akai ame-ga}>)^{L}$
NOT: $*({}^{L}<{}^{H}\text{amai akai ame}>)^{L}$

At play here is an interface constraint sensitive to syntactic branching (Kubozono, 1993):

(13) Align- L (X^{br}, MiP).
The left edge of a branching constituent in syntactic structure corresponds to the left edge of a minor phrase in prosodic structure.

These two syntax–phonology alignment constraints outrank Binary MiP in the grammar of Japanese, causing the violations of Binary MiP seen in (10) and (12):

(14) Align-L (XP, MaP), Align- L (X^{br}, MiP) ≫ Binary MiP.

It is because neither of these interface constraints is applicable in the left-branching structure of the subject noun phrase in (8) that we see the effects of the lower-ranked Binary MiP emerge there. In other words, where the lower-ranked Binary MiP is not forced to be violated by the higher ranked interface constraints, it produces effects that are *complementary* to the effects of the interface constraints.

We also find cases where an expected effect of a syntax–phonology interface constraint *fails to appear* because of pressure from a competing prosodic markedness constraint. This can be modeled by ranking the prosodic constraint higher than the relevant interface constraint. (15) shows the expected MaP break at the left edge of VP in a neutral Focus sentence in Japanese.

(15) A neutral Focus sentence in Japanese

Sentence (16) contains a text which differs only in having a contrastive Focus on the last word of the subject NP, *ani'yome*. The phonological domain structure of this sentence shows an absence of the syntactically expected MaP break at the left edge of the VP, as well as the unexpected presence of a MaP break at the left edge of the Focus constituent (Poser, 1984; Pierrehumbert and Beckman, 1988; Nagahara, 1994).

(16) The same sentence, except with *aniyome* as FOCUS.

Truckenbrodt (1995) argues that the source of these phrasing effects in Focus sentences lies in a syntax–phonology interface constraint calling for a Focus to be more prosodically prominent than any other element within the Focus domain.

(17) Focus Prominence
The string in PR which corresponds to a string in PF dominated by Focus must contain a prosodic prominence that is greater than any other prominence contained in the Focus domain.

In the case where the domain of the Focus is the entire sentence, as in (16), respect of this constraint means that the Focus element and all the prosodic phrases that dominate it will be the head(s) of the intonational phrase corresponding to that sentence in PR (underlined). A prominent constituent is subject to a prosodic markedness constraint that calls for it to be aligned with an edge of the superordinate constituent (McCarthy and Prince, 1993). The violation in (17) of the interface constraint (11) calling for a MaP edge at the left edge of VP is claimed to be driven by the higher-ranked prosodic constraint Align-R (MaP_{head}, IP).

This constraint calls for the prominent MaP in the IP that dominates the Focus in (17) to align with the right edge of the intonational phrase, and so prevents the existence of any other MaP following the Focus. This analysis is captured in the ranking in (18).

(18) Focus Prominence, Align-R (MaP_{head}, IP) ≫ Align-L (XP, MaP).

So, here, a syntactic effect is overridden by a prosodic effect.

Speech Rate

One additional sort of nonsyntactic factor on phonological domain structure that has been recognized for some time in the literature is speech rate. In Bengali, a faster speech rate gives rise to larger phonological phrases (see Section Domain Convergence). Speech rate plays a role as well in MiP organization in Japanese; in slower speech, single words may easily constitute a MiP (Selkirk and Tateishi, 1988). Since syntactic structure does not vary with speech rate, these

rate-based differences in phrasing give additional evidence for an autonomous, nonsyntactic, prosodic structural representation of phonological domains.

The Syntax–Prosodic Structure Interface: Serialist or Parallelist?

The classic generative model of the relation between syntax and phonology is an input–output model, in which surface syntactic representation, the output of the syntactic component, is input to the phonological component, whose output is the surface phonological representation. Most approaches to modelling the syntax–prosodic structure interface have assumed this serialist, unidirectional, input–output model, with the prediction that syntax may influence phonology, but not vice versa. They have posited constraints, algorithms or rules relating the two representations which have the general form 'If the surface syntactic representation of the sentence has property S, then the surface phonological representation will have property P.'

In the Align/Wrap theory of the interface (Selkirk, 1986, 1995; Truckenbrodt, 1999), the demarcational Align class of constraints calls for the edge of any syntactic constituent of type C_S in the surface syntax to align with the edge of a prosodic constituent of type C_P in the surface phonology, while the cohesional Wrap class of constraints calls for a syntactic constituent of type C_S in the surface syntax to be contained within a prosodic constituent of type C_P in the surface phonology. There have been other, relation-based, proposals concerning the nature of syntax–prosodic structure interface constraints as well, including Nespor and Vogel, 1986; McHugh, 1990; Kim, 1997, all understood to be consistent with the prosodic structure hypothesis, and with the input–output architecture.

An input–output model of the syntax–phonology interface makes the essential claim that constraints on phonological output representation do not interact with constraints on the surface syntactic representation. Two sorts of apparent challenges for the input–output model have recurred in recent literature. One sort concerns clitics whose distribution is governed by both syntactic and prosodic constraints, such as the second position clitics of Serbo-Croatian (Inkelas and Zec, 1990). Yet because the syntax itself affords options in the positioning of second position clitics, it is not necessary to construe the prosodic subcategorization of a clitic as outranking a constraint on syntactic word order. Another sort of challenge concerns the alleged dependence of word order on the positioning of focus-related prosodic prominences in the sentence, as suggested by Vallduvi (1991) for Catalan, or Zubizarreta (1998) for Spanish. However, since the latter sort of phenomenon potentially can receive a purely syntactic treatment in which the Focus properties of syntactic representation are crucial in determining word order (see, e.g., Grimshaw and Samek-Lodovici, 1998), this sort of case is not yet compelling. It remains to be seen whether the syntax–phonology interface is an input–output relation or whether it is instead a two-way street.

Syntax–Semantics Interface

Erkki Luuk, University of Tartu, Tartu, Estonia; and Stockholm University, Stockholm, Sweden

© 2015 Elsevier Ltd. All rights reserved.

Abstract

I introduce the topic by pointing out some common problems and disagreements in defining the notions of syntax and semantics. Avoiding theory-specificity and adhering to no particular linguistic school, the article makes minimal assumptions about the notions to arrive at a description of syntax–semantics interface. Among the topics discussed are logic, truth, meaning and their relevance to syntax and semantics, syntactic and semantic validity, and semantics' relations to core areas of syntax (word order, grammatical relations, and constituency). The main claims are (1) a robust correlation between semantic and syntactic validity and (2) that grammatical relations and constituency are largely determined by semantics, while certain forms of word order are autonomous.

Introduction: Syntax/Semantics

The notions of syntax and semantics are widely used beyond linguistics (e.g., in mathematical logic and computer science, not to mention their colloquial usage) but the present article focuses on their application on natural languages (Semantics). In linguistics, the notions are by no means strictly defined, and estimates as to what is what and where to draw the line between the two vary considerably (Jackendoff, 2002: pp. 268–277). Thus, at this stage, it is useful to think of the domain we are interested in as syntax/semantics, and to keep in mind that different theories partition it into syntax and semantics in different ways. A (or perhaps the) crucial difference between different schools is whether phrasal and sentential semantics is allowed. In generative grammar (originating in Chomsky, 1964 [1957]), at least in its recent emanation (Berwick et al., 2013), only lexical items (basically, words and morphemes) can have semantics (*see* Generative Grammar; Lexicon). By contrast, there are approaches focusing mainly on phrasal and sentential semantics, e.g., frame and formal semantics and semantic syntax (originating in Fillmore, 1976; Montague, 1970; Seuren, 1996, respectively). This picture is further complicated by the fact that syntax and semantics are already very different by their nature (see Sections Syntax; Semantics; and Syntax–Semantics Interface: Preliminaries for details). While everybody regards meaning as central to semantics, views on what is (central to) syntax are much more variegated. Syntax has at least three distinct focal parts – word order, grammatical relations, and constituency – and their roles, contents, and interrelations are widely debated by different theories (see Sections Constituency; Grammatical Relations; and Word Order for details; (cf Word Order; Grammatical Relations)). In some ramified approaches to sentential semantics, it may be possible to derive grammatical relations and hierarchical sentence structure (constituency) from semantics, leaving only the cross-linguistically highly variable word order for syntax. The gulf between what could be termed as syntacto- and semantocentric views on syntax/semantics is also evident in their claims about the universality of syntax or semantics. For generative grammarians, syntax is universal and semantics (except for the general principle of form-meaning relation) highly language-specific, while a semantocentric view is the direct opposite. In addition, the approaches have generally opposing research agendas. As referred above, a semantocentric agenda is largely shaped by questions like how much of constituency, grammatical relations, and word order can be derived from semantics and pragmatics. By contrast, in the history of generative grammar, the role of semantics has gradually diminished and the function of syntax expanded (cf Berwick et al., 2013; Chomsky, 1964[1957]; Jackendoff, 2002).

Due to innumerable fundamental discrepancies between different approaches and schools, as well as for some peculiarities of natural language and its study, it seems impossible to give an objective overview of syntax/semantics, much less of the syntax–semantics interface. However, if we ever plan to get anywhere with this we would better start somewhere.

Partitioning Syntax/Semantics

To arrive at a description of syntax–semantics interface, we must start with a few axioms about syntax and semantics. Given the state of theorizing in this field, one cannot hope for our axioms to be both strong and universal (or uncontroversial); nevertheless, if we want to progress we have to posit some. In reading indiscriminately what has been written about syntax/semantics in the last few hundred years, one may observe the following general principle:

1. Syntax pertains to the ordering of elements, while semantics deals with their meanings.

Usually, the 'elements' are meaningful elements – thus, for example, the ordering of phonemes does not belong to syntax. However, this is by no means uncontested. According to Berwick et al. (2013), syntax is also responsible for the ordering of phonemes. Admittedly, this is something with which no other approach that I know of concurs. Besides, when viewed like this, the scope of syntax would be much wider than that of semantics, which deals only with meaningful elements by our definition. Thus we are tempted to set the additional condition:

2. The elements in (1) are meaningful.

From (1) and (2), one can deduce an important dependency:

3. Syntax depends on semantics but the converse does not hold.

As a test that the converse does not hold, take any known word in natural language, and observe that it has meaning irrespective of its context. This follows from the definition of elementary word: a minimal unit of language understood (but not necessary used) outside context (Luuk, 2010). As another test, consider the sentence:

4. *He teached them*,

which is morphosyntactically (see Section Syntax) invalid but semantically valid (i.e., readily understood). We end this section with an observation which, although not particularly illuminating or important, is still worth mentioning: Both the objects of study and the disciplines studying them are called syntax and semantics, so we should alert ourselves to this potential difference in these words' meanings.

Syntax

The context, i.e., the ordering meant (and studied) by syntax, is fundamentally determined by the condition of temporal representation over serial channel. In spoken languages this manifests itself as a sequence of sounds, in written language as the scanning sequence in reading, in signed language as a sequence of manual signs. There is a subtle point as to whether the order of morphemes (the smallest meaningful units in natural language) belongs to the domain of syntax. On one hand, many morphemes are words, but on the other hand, there is an entire discipline (and level of language) – morphology – generally viewed as distinct from syntax dealing with them (*see* Morphology in Linguistics). In fact, quite a few researchers would be willing to dismiss syntax and morphology as independent disciplines altogether and speak of morphosyntax instead (cf Hengeveld and Mackenzie, 2008). From a logical viewpoint, as a study of orderings of linguistic signs, morphosyntax would make perfect sense. (In this article, linguistic sign and linguistic expression mean the same.) However, unfortunately 'morphosyntax' has been used in another sense already, and for historical (as well as synchronic, typological, and terminological reasons) syntax has, at least for the last 100 years, vastly overshadowed morphology. For a major typological reason, there are languages like Classical Chinese that admittedly lack morphology (in the sense of lacking morpheme compounding, not in the sense of lacking morphemes, which would be impossible for any language). On the other hand, no language could lack syntax because no language lacks words, the main building blocks of syntax (note that word compounding is never an issue, and probably lacking in a vast number of languages). Thus the reason for this superiority of syntax is an important definitional asymmetry: syntax is mainly about word ordering, while morphology is about morpheme compounding and ordering. This last 'and' makes morphology's domain much more restrictive, essentially equating it with the intersection of morpheme compounding and morpheme ordering. The domain of syntax is more elementary, although in the analysis of levels (of linguistic representation, semantics, etc.) morphemes are more elementary than words.

The vast majority of syntactic rules are language-specific (see Section Syntax–Semantics Interface: Preliminaries). However, some cross-linguistically universal synchronic (e.g., (1), (7), and head-dependent relation – see Section Constituency) and diachronic principles remain. In general, the syntax of any language at a particular moment is partly coincidental and partly determined by the phase of grammaticalization cycle that the language is currently in (cf Grammaticalization). By coincidental I mean the result of a complex interplay of diverse historical factors such as migration, occupation, technology, war, language contact, language prestige, true accident, etc. that we will never disentangle (cf Language Contact).

Semantics

When one considers levels of linguistic representation – phoneme, morpheme, word, phrase, sentence, and discourse – semantics pertains uniformly to all of them except phoneme. Put differently, all these five levels have meaning, thus semantics by (1). However, the meaning constructed (or extracted) on one level may in some respect differ from that on the others. Semantics is uniform in the sense that it has only one general rule:

5. Form-meaning correspondence.

Note that this view of semantics does not address the definition of meaning, which must be specified separately (see Section Predicates, Arguments, and Meaning). The universality of rule (5) (essentially, a definition of sign) stretches far beyond language, as (5) describes all natural and artificial communication systems. Semantics is also uniform in the sense that it is cross-linguistically universal (as testified by the possibility of translation – cf Haspelmath, 2007). Succinctly speaking, semantics is a function that, given a form as input, returns its meaning(s) – assuming there are any. If there is more than one meaningful input, the relation will attempt to compose the meanings of its arguments. For example, as the sentence is a combination of meaningful units, its meaning is generally compositional (as usual in language, there are few exceptions, like *it rains*, where *it* has clearly no meaning whatever – although *it* as a pronoun has a meaning). On the other hand, the meaning of a morpheme is usually elementary (of which there is a plethora of examples, e.g., the noun stem *cat* or the noun class (or gender) markings for feminine and masculine). Several other morpheme types (e.g., most cases, adpositions, tense-aspect-mood) mark relations between more than one input, and have thus compositional meanings involving predicates with two to four arguments. Four arguments seem to be (close to) the attested grammatical maximum, probably due to the constraints on short-term memory (Cowan, 2001).

Predicates, Arguments, and Meaning

Mathematically, predicate is a function from a set A to a special two-element set. In the context of language (and mathematical logic), the two elements are usually taken to be true and false (cf Logic and Linguistics). Assuming that the values are true and false, and since function is a subcase of relation, predicates describe the truth or falsity of relations. In the

simplest case, the relation could be, e.g., belonging to a subset B of A. If this is the case, the predicate P that represents the relation is true of an argument x (usually written P(x) or Px) iff x is an element of B and false (¬Px) otherwise. In this case we say that P is the characteristic (or indicator) function of B. Thus, predicates are a convenient way of addressing truth, falsity, sets, relations, functions, and (other) predicates. Given all this, it might occur that they are also a convenient way of addressing meaning. In the traditional model-theoretic sense, the meaning of a sentence is its truth-conditions (Davidson, 1967). In a more refined (but still entirely model-theoretic) sense, the meaning of a sentence is the proposition expressed by the sentence as the set of circumstances in which it is true (Soames, 1992: p. 29). Admittedly, I have a difficult time distinguishing these definitions, but they are purportedly different (Soames, 1992), so it makes sense to mention both. In either case, meaning boils down to a set of circumstances. Now circumstances are relations, and relations can be expressed as predicates – which is all the more appropriate since the circumstances are required to be true (and it is difficult to get around with truth without predicates). The frequent argument that only (declarative) sentences can have meanings is immaterial, because one can take, e.g., *cat* as a one-place predicate (which is true if used in reference to the right type of creature). In a suitable context, even a single word can produce a reference. Also, one should not be too daunted by the standard counterargument to this type of theory of meaning, concerning the truth-conditions of sentences that are always true (such as *it rains or it does not rain or both* and *1 = 1*). It is namely claimed that all such sentences have exactly the same truth-conditions, whereas in fact there are ways to filter out the relevant circumstances (but we will not delve further into this issue here). In sum, we seem to have a mathematically precise way of addressing meaning as a (set of) predicate(s). Note that this does not tell anything about how or whether these predicates are implemented in the brain, so there is no conflict with representation or concept-based theories of meaning (of which there are many – e.g., Gärdenfors, 1998; Jackendoff, 2002; Langacker, 1990; Luuk, 2013a). After all, predicates are somehow implemented as concepts in our consciousness. If so, why could not they be implemented on some lower conceptual level? (See Hurford (2003a,b) for a claim that predicates and arguments can be distinguished on a perceptual level already.)

Syntax–Semantics Interface: Preliminaries

Both semantics and syntax are rule systems but the rules involved are very different. As we saw above (see Section Semantics), there is only one general rule in semantics, holding far beyond natural language. Differently from animal communication systems, there is usually no one-to-one correspondence between linguistic form and meaning (Ferrer-i-Cancho et al., 2005). This (possibly) unique property of natural language facilitates expressivity, creativity, ambiguity, and making mistakes. Syntax, on the other hand, is a relatively complex

6. combinatorial system of dependency, agreement, and linear ordering rules,

the sole purpose of which appears to be mapping meanings to a serial channel (by (1)). Differently from (5), (6) and even the weaker (7) are uniquely human. In addition, the vast majority of syntactic rules are language-specific, and only a tiny fraction of them is known, because there are (or recently were) 6000–7000 languages in the world. The staggering typological diversity of syntactic rules is a testament to the degree of freedom the meaning mappings have. Indeed, it seems as if anything is allowed as far as the rules strike a (sub)optimal balance between minimum effort and maximum precision. This is a complex task, with trade-offs in at least three dimensions: both for the speaker and hearer individually and between them (producing vs processing effort). The sole criteria for such a balance seem to be communicative and propagative success (by the latter is meant the propagation rate of a syntactic structure in the community).

In a sense, "mapping meaning to a serial channel" is an understatement – if a mere mapping would be involved in syntax, a sequence (a concatenation) of signs would do. Granted, perhaps not any sequence but, even if we constrain the sequences, the core of full syntax does more than just concatenate signs – it also compounds and embeds them. The difference between concatenation and compounding is that in the latter the signs are necessarily interpreted together. The difference between compounding and embedding is that only the latter allows for center insertion and (potentially) more than two-level nesting. Note that embedding has a broader definition (a meaningful unit in another meaningful unit) here than in the traditional syntactic literature. For example, a morpheme in a word is an instance of embedding in this broader sense.

As mentioned above, differently from the principle of semantics (5), the principle of syntax:

7. a combination of meaningful elements by (morpho-) syntactic rules,

is uniquely human (Hurford, 2004; Jackendoff, 1999; Ujhelyi, 1998). This claim is not particularly surprising, given that (morpho)syntactic rule as such is uniquely human (if we adhere to definitions (1) and (2) – if phonological sequences are included in syntax, birds may have it). Thus syntax must have emerged relatively recently by the evolutionary scale. In fact, we have also some evidence to base our conjectures on how it evolved. For example, it can be shown that syntax evolved from concatenation to compounding to embedding, whilst retaining all the preceding procedures (Luuk and Luuk, 2014). As virtually all modern analyses concur, protolanguage started with few isolated signs (cf Bickerton, 2007; Jackendoff, 1999; Johansson, 2006). Only after that could certain rules be applied to them. Despite possible claims to the contrary (Bickerton, 1998; Chomsky, 2010), it is implausible that a complex rule system like syntax emerged suddenly full-fledged as a result of some mutation or otherwise. A gradualist scenario is much more likely (Pinker and Bloom, 1990). To be precise, the claims (at least that of Chomsky) are about the abrupt emergence of language faculty, the core of which would be a capacity for syntax. This is something completely different from an abrupt emergence of full syntax

in a linguistic community, which, as said, is implausible (and probably also impossible).

Syntactic and Semantic Validity

It is frequently claimed that syntax and semantics are two entirely different systems, domains or dimensions, which have little (if anything) in common except for the need for a common interface. This may be so – since (and as long as) the notions are not strictly defined, not much seems to hinge on the truth or falsity of this claim anyway. Another frequently advanced claim is that there is a double dissociation between syntactic and semantic validity. If this were the case, we would have rather substantive evidence for syntax and semantics being autonomous systems of linguistic representation. As the claim about dissociation seems quite well-articulated, we might be even able to test it. So let us examine this claim in more detail.

We mentioned above the principle of syntax: a combination of meaningful elements by (morpho)syntactic rules. It has been allegedly shown that this function can be separated from semantics. The commonest example is (Chomsky, 1964[1957]):

8. *Colorless green ideas sleep furiously.*

This is taken to be an example of a sentence that is syntactically valid but meaningless (that is, presumably, semantically void). However, the truth-conditions for this sentence (the circumstances under which it could be true) are

9. If green could be colorless and ideas green, and if sleep could be furious and ideas sleep (then (8) could be true).

If we accept the standard model-theoretic stance that truth-conditions are (or yield) the meaning, the meaning of (8) is somehow given by (9). The circumstance that the relations in (8) happen to be false in our world is irrelevant. Whether or not a truth-condition is satisfied in a (or in any) model is immaterial for its existence. What is required is a structure where it can be interpreted. Observe that the actual world is such a structure since it has all the necessary predicates (coinciding with the words in (8)). This structure allows for the interpretation of the meaning (i.e., truth-conditions) of the sentence (8) that is always false in the structure. After all, if it did not, how would one know that the sentence is false in the actual world?

In sum, and in light of what we said about the asymmetric dependency between syntax and semantics (3), one is led to the view that all syntactically valid expressions are also semantically valid but not vice versa. As a further test, consider the strings

10. *askldfjkldjkl sdfaklj fkkdfj*
11. *the wug drunted geperfully*
12. *you runs*
13. *this is a house*

(10–13) exhibit a gradation of general semantic/syntactic validity (well-formedness, if you will) from zero to maximum. In each of them, a robust correlation between syntactic and semantic validity is evident. In (10), both are (near) zero. Pseudo-expressions like (11) are sometimes erroneously viewed as examples of syntax–semantics dissociation. In fact, it is easy to see that everything syntactically valid about (11) is also meaningful, i.e., valid semantically. Let us try to analyze this string, starting from syntax. First, there is the noun phrase (NP) *The wug*, signaled by the article as well as 'word' order. Second, the 'verb' *drunted* – technically not an English verb but readily interpreted as one owing to the past tense suffix *-ed* and 'word' worder. Finally, the 'adverb' *geperfully* modifying (as adverbs do) the 'verb.' We do not know how exactly it does that but a modification (as such) is evident. Like the 'verb,' the 'adverb' is signaled by a suffix (*-fully*) and 'word' order. Now turn to semantics. It is not difficult to see that all we said about syntax reflects in the string's meaning. In fact, everything in (11) except for the 'stems' *wug*, *drunt*, and *geper* is meaningful. We have a definite (*the*) agent that was engaged in an activity (in a loose sense) in a specific way (although we do not know, which) in the past. Admittedly, this is a lot of meaning (as compared to, e.g., (10)), and the fact that it was extracted mostly from syntactic rules and categories does not make it less valid. It merely shows that not only stems but all morphemes and even specific word orders (such as *the x*) have meaning, and that semantics probably cannot be dissociated from syntax (while the converse is possible by (3)). (12) is defective morphosyntactically (the agreement failure) and semantically (2nd and 3rd person clash), but its syntactic and semantic interpretations are constrained much better than those of (10–11). In fact, only three readings suggest themselves – *you run*, *your runs*, and *(s) he runs* – so as compared to the previous examples the expression seems more ambiguous than invalid. (13) is valid syntactically and semantically. In sum, there is a robust correlation between syntactic and semantic validity in all examples (cf Kako and Wagner, 2001), corroborating the claim or suspicion (whichever you prefer at this point) that syntax is not an autonomous system of linguistic representation.

Constituency

Constituency refers to the whole–part relation in language expressions. Although one may speak of phonological and morphological constituents, the term 'constituent' has a predominately syntactic usage, being mainly reserved for words, phrases, and sentences. In the context of syntax, constituent structure thus refers to words, phrases, or sentences in a hierarchical structure. There are numerous ways to model constituent structure of natural language. This (besides modeling grammatical relations – cf Section Grammatical Relations) is a bread-and-butter work of theoretical linguists, and most grammatical theories also stipulate their specific constituent structures. Likewise, there is no shortage of methods for describing them (e.g., trees, rewrite rules, bracketing, predicate logic, frame semantics, lambda calculus, categorial grammar, model theory, etc. (cf Logic and Linguistics)). Far from being equivalent or complementary, the methods frequently lead to very different views on syntax, semantics, and their interface.

The single most important (i.e., widespread and universal) morphosyntactic rule is head-dependent relation. The essence of a head-dependent relation is that in combining two linguistic units (e.g., in a word or phrase), one of them 'projects' or starts governing the other (although it may be not easy to determine

which one). The one projecting is called the head and the other is dependent. Since every head-dependent relation specifies two whole–part relations and three constituents, head-dependent relation yields constituency for free. Since agreement marks syntactic constituents, head-dependent relation provides also the foundation for agreement (cf Grammatical Agreement). In natural language, head-dependent relation and constituency go far beyond syntax, possibly even to phonology. An interesting question for syntax–semantics interface is what determines which elements become heads at phrase and sentence levels. At least in some cases semantics has probably some role in it. For example, the finite verb or flexible (see Luuk, 2010) is the head of the clause and the clause predicate, suggesting that the head may be determined by the semantic predicate-argument structure. Another example is agreement. Lehmann (1982) has argued that only constituents that relate to the same referent may overtly agree with each other.

Grammatical Relations

Grammatical relations (or syntactic functions, as they are sometimes also called (*see* Grammatical Relations)) hold between clause constituents. Standard constituents in this sense are verb, object, and subject but there are others like modifier, specifier, determiner, etc. (there are many others, most of them specific to particular grammatical theories, of which there are more than 100). Every grammatical relation is stipulated by at least one head-dependent relation (see Section Constituency). A crucial question is how much of grammatical relations are derivable from semantics. As it turns out, a lot. The Chomskian term for this phenomenon is theta criterion: each argument of the (finite) verb is assigned exactly one theta role (semantic role, e.g., agent, patient, goal, etc.) and vice versa. Because of this one-to-one correspondency, it seems that the two – semantic role and syntactic argument – are merely two facets of the same thing, viz. meaning and ('syntactic') form, respectively. But if so, then grammatical relations are fundamentally semantic phenomena, because form-meaning is the general principle of semantics. Furthermore, the supposedly syntactic relations like V, S, O, etc. can be also described with semantic roles in frame semantics or predicates and arguments in a suitable predicate logic. A closely related notion used in generative grammar and elsewhere is subcategorization frame, identifying finite verb's potential positions in phrase structure trees by its class (intransitive, transitive, ditransitive, ergative, etc. (cf Valency and Argument Structure in Syntax)). In generative grammar, subcategorization frame (detached from the verb that appears in it) was believed to be meaningless. However, Kako (1997) experimentally showed this not to be the case (with stimuli resembling (11)). Since subcategorization frames have meanings, it seems that a core part of syntax is semantically driven.

Word Order

All possible (S, V, O) word orders have been attested in the world languages, although some are very rare (the *World Atlas of Language Structures*, http://wals.info/chapter/81; (*see* Word Order)). In languages with (relatively) free word order, semantics and especially pragmatics (e.g., information structure) are responsible for at least some ordering principles. In languages with fixed word order, semantics has probably a minor role in it. The reason for this is that natural language semantics is order-neutral – nowhere except in formal notations is there a rule to the effect that a predicate should follow its argument(s) or vice versa. If a verb has three arguments (like *give*), it probably makes sense (for processing considerations at least) not to put the indirect object first but this is a pragmatic rather than semantic constraint. Granted, certain fixed orders are meaningful as they specify constituents with specific meanings, be they referents (such as *the x* mentioned above) or relations (e.g., subcategorization frames and prepositional phrases – cf Luuk, 2013b). However, there is no semantic reason for choosing this particular order – we could have determiners following nouns and postpositions instead of prepositions. So, of all the syntactic phenomena we have discussed, at least fixed word order seems largely independent from semantics (and other levels of linguistic representation), thus qualifying syntax as an autonomous level after all (cf Section Syntactic and Semantic Validity). Although we have so far concentrated on cases of semantics determining syntax (partly because they are more difficult to see), this qualification allows us, at least in languages with fixed word order, to consider also the converse cases. There are many such examples, e.g.,

14. *j loves m*
15. *m loves j*

Conclusion

As was noted in the beginning (cf Section Introduction: Syntax/Semantics), an objective account of the syntax–semantics interface of natural language seems unattainable. Although I have tried to shun all major schools and to keep my assumptions to a minimum, I do not know how successful or convincing my case has been in this short introduction to what must be one of the most obscure, complex, and technical areas of natural language. This obscurity and complexity is due to several reasons, which for this particular field unhappily coincide: the great number of opposing linguistic schools; the still greater number of specific grammatical theories; the direct relevance of grammar (and hence of grammatical theory) for a description of syntax–semantics interface; the field's uncomfortable position between two established (yet arbitrarily defined) linguistic levels, hence dependence from both; the relatively central position with regard to all levels (and thus a near-maximum dependency from all of them (and hence also of their descriptions, of which there are many)); and lastly (but most importantly) the scarcity of clear, universal definitions and the (maybe even necessary) lack of a theory-neutral research program. One can only hope that perhaps in a not-so-distant future someone will succeed in advancing this area beyond mere wishful thinking and haphazard theorizing. On a more optimistic note, the great number of linguistic schools and grammatical theories in itself is rather positive – the more theories we have, the greater (albeit likely still very low) the probability of least one of them being (sufficiently) correct.

Systematic Reviewing and Meta-Analysis

Jeffrey C Valentine, University of Louisville, Louisville, KY, USA

Abstract

The methodologies of systematic review and meta-analysis were developed to address the challenges of providing a transparent and replicable review of the research literature relevant to a particular question. In this article we provide a brief overview of systematic reviewing and meta-analysis and then discuss how to develop a good research question for a review, how to search for relevant studies, and how to extract information from the studies (including information that will help judge study quality). The second half of this article concerns meta-analysis specifically (i.e., the statistical synthesis of the results of the studies obtained through the systematic review process), including weighting, computing a mean effect size, conducting a homogeneity analysis, and carrying out moderator analyses. The article concludes by discussing new developments in meta-analysis.

Introduction

Imagine that you are responsible for finding programs that occur outside of the school day for students who are at risk of school failure. Among other options, you think about the possibility of mentoring – that is, connecting a responsible adult volunteer (the mentor) with an at-risk student (the mentee), with the goal of fostering positive development and well-being in the student (DuBois et al., 2011). But you might wonder if mentoring is an effective model for reducing school failure. It is relatively easy to find anecdotes on the Internet that attest to the power of mentoring. For example, the Web site for Big Brothers/Big Sisters of America relays an anecdote about a child, Deva, who was the first in her family to receive an academic scholarship (http://www.bbbs.org/site/apps/nlnet/content2.aspx?c=9iILI3NGKhK6F&b=6195821&ct=9103913&notoc=1). Anecdotes are useful ways of connecting readers to the experience of the participants, but it is difficult to discern the typical effects of an intervention from such stories. As such, you might look for studies that evaluate the effects of mentoring programs. The Web site for MENTOR, the National Mentoring Partnership, stated that a study by Herrera et al. (2013) found student "gains in social acceptance, academic attitudes and grades" (http://www.mentoring.org/about_mentor/value_of_mentoring). But one study, no matter how well conducted, is limited. You might therefore wish to find a literature review that examines a broader range of studies. For example, the review by Lawner et al. (2013) examined 19 studies of mentoring programs and concluded that the results of mentoring programs on educational outcomes are 'mixed.' But even when statements about effects are drawn from a range of studies as they were in the Lawner et al. study, it is often not clear how representative the studies are and how rigorously the findings from the individual studies have been synthesized.

The methodologies of systematic review and meta-analysis were developed to address these challenges by providing a transparent, replicable, and systematic review of the research literature relevant to a particular question. In the sections below we provide a brief overview of systematic reviewing and meta-analysis and then discuss how to develop a good research question for a review, how to search for relevant studies, and how to extract information from the studies (including information that will help judge study quality). The second half of this article concerns meta-analysis specifically, which refers to the statistical synthesis of the results of the studies obtained through the systematic review process.

Steps in the Systematic Review Research Process

A systematic review looks a lot like any other type of research (Cooper, 1982): Researchers need to formulate a good research question, develop a sampling plan and collect data, analyze the data, and report the results. Of course, the way that these steps are operationalized will differ if one is carrying out a primary study or a systematic review. For example, the sampling plan in a systematic review involves identifying potentially relevant research literature. The main point is that the framework should feel very familiar, and we just need to flesh out how these generic steps are implemented in the context of a systematic review.

Formulating a Good Research Question

Coming up with a good research question is a skill unto itself. Depending on the aims of the review, a question can be narrow (e.g., "What is the effect of the Big Brothers/Big Sisters mentoring model on academic achievement for urban girls aged 13–17?") or broad ("What is the effect of mentoring on outcomes for children aged 3–17?"). Narrow and broad questions typically lead to very different types of systematic reviews. DuBois et al., working with a broad research question, identified 73 studies for inclusion in the review. A scholar interested in synthesizing studies on a narrow question like the one posed above would find only a few studies. Indeed, a research question can be so narrowly tailored that no studies have ever been done that examine it. In general, narrow research questions are best when the interest is in examining the effects of a specific intervention (e.g., the Big Brothers/Big Sisters mentoring

model). Broad questions are usually best when the goal of the research is knowledge generation. For example, the scholar might be interested in identifying common elements in effective mentoring programs. A broad research question that includes many different models will be a better way of doing this than a narrow review will. For example, there might be interest in determining whether providing mentors with training matters. If a review just focuses on the Big Brothers/Big Sisters model, this question cannot be answered because that particular model mandates mentor training (so there is no variation on this dimension).

Setting Eligibility Criteria: PICOS

One way to think about a research question is that as much as possible it should specify the Participants, Intervention, Comparison, Outcomes, and Study types of interest, and thus go a long way of describing the characteristics of studies that will lead to study inclusion, and those that will lead to exclusion from the systematic review. Think about the narrow research question posed above. It explicitly specified the participants (urban girls), the intervention (mentoring as practiced by Big Brothers/Big Sisters), and the outcomes (academic achievement) of interest. The review question also implies that experiments will be examined (by asking "What is the effect of …"), and we can therefore assume that children who receive Big Brothers/Big Sisters mentoring will be compared to children who do not. Of course, researchers still need to make some decisions – for example, they need to operationally define what they mean by 'urban,' but many of these kinds of decisions will be relatively easy to make.

As the review question broadens, however, eligibility decisions are less likely to follow explicitly, and boundaries distinguishing between studies the reviewers would like to include and studies the reviewers would like to exclude are often harder to define. Consider the broad research question we posed above, which asks (in part) "What is the effect of mentoring …?" To carry out a systematic review of studies that examine mentoring (broadly defined), the reviewers have to decide what they mean by 'mentoring.' As an example, DuBois et al. (2011) defined a mentoring as one that pairs a youth in a one-to-one relationship with a volunteer adult, with the goal of fostering a relationship that enhances the youth's well-being. As such, studies that involve paid mentors, or have an explicit goal of helping the youth find a job, or involve a single mentor with multiple youths were not included in their review.

Logic Models Can Help with Problem Formulation and Eligibility Setting

Usually based on both theoretical and empirical considerations, logic models describe the connections between different determinants of an outcome, and how these determinants are related in a specific intervention (Anderson et al., 2011). A simplified version of the logic model used in DuBois et al. (2011, p. 61) looks like this: A strong and meaningful mentoring relationship develops the youth's mutuality, trust, and empathy. The development of these traits leads to positive socioemotional, cognitive, and identity development. These positive developments then lead to outcomes such as improved grades and social behavior. To see how the articulation of a logic model can shape the review question and eligibility criteria, consider the 'strong and meaningful mentoring relationship' component from the logic model developed by DuBois et al. A 'strong and meaningful' criterion implies that the intent of the mentoring program should be to foster deep, long-term relationships. Therefore, studies of mentoring programs that establish only short-term relationships were not included in DuBois et al.'s review (in essence, the type of mentoring examined in those studies is not the same type of mentoring that DuBois et al. were interested in researching). Decisions regarding where to draw fuzzy boundaries like these are facilitated by the articulation of a clear logic model.

Searching for Relevant Literature

Once a specific review question has been formulated and the inclusion criteria have been set, the next step involves locating studies that might be eligible for review. As a general rule, individuals carrying out a systematic review should attempt to find *every* study that meets their inclusion criteria. For most research question this is a daunting task, and in fact we will almost never know if we have attained our goal. A more reasonable goal might be to minimize the differences between the studies that we are able to collect and the studies that we could not locate. We try to minimize the differences between studies we identify and those we cannot identify by using multiple complementary literature search strategies. A search carried out in multiple electronic databases (like PsycINFO) is likely to be the backbone of the literature search strategy. However, systematic reviewers are advised to use other techniques to supplement this search. For example, in most cases multiple databases should be searched. And, it is almost always important to look beyond databases for potentially relevant studies. For example, literature retrieval experts often recommend sending requests to the listservs of relevant professional organizations, contacting authors of studies that are included in the review, and conducting targeted Internet searches (Campbell Collaboration policy brief). These strategies might help uncover studies that are unavailable through the usual routes – for example, studies that are currently under consideration for publication, or studies that authors have decided not to submit for (or have given up on) publication.

There are several reasons that individuals undertaking a systematic review are advised to go to such lengths to uncover potentially relevant studies. Having more studies generally increases statistical power, and will also usually serve to increase the generalizability of the results (because these are based on a wider variety of study characteristics). Just as important as statistical power and generalizability, it has been shown that studies that are not published tend to have smaller effects than studies that do get published, a phenomenon known as publication bias. Publication bias occurs because studies lacking statistically significant findings on their main outcomes are less likely to be submitted for publication, and if submitted less likely to be published, than studies with statistically significant results on their main outcomes. Statistical significance is a function of two things: (1) the size of the sample used to estimate the effect and (2) the magnitude of the effect. As a result, small studies that just happen to observe very large effects are more likely to get published than small studies that observe smaller effects. Because unpublished studies are

harder to find, small studies with small effects will tend to be missing from the meta-analytic database, creating a bias in the estimate of the effect. Therefore, individuals undertaking a systematic review should invest significant effort into finding studies that have not been published and evaluate them for potential inclusion in the review.

Screening and Coding Studies

Because literature searches have the goal of locating as many relevant studies as possible, they are necessarily broad. One side effect of a broad search is that it will likely identify many more potentially relevant than actually relevant studies. As a result, once the literature search has been carried out, the potentially relevant studies need to be screened for relevance. For studies identified through Internet and electronic database searches, screening is usually based on information available in the titles and abstracts of the studies identified as being potentially relevant. The goal of the screening process is to weed out any studies that are *clearly* not relevant. DuBois et al.'s (2011) search for mentoring studies turned up documents that were not studies (e.g., opinion and advocacy pieces), studies that did not involve mentoring as it was defined by DuBois et al. (e.g., tutoring), and studies that did not involve an adult mentor (e.g., peer mentoring). Studies that are not screened out at this stage are obtained, and a final relevance decision is made based on information available in the full text of the document.

Once a set of studies has been identified as being relevant to the review, they need to be coded. The coding process is analogous to collecting data on a survey questionnaire (Lipsey and Wilson, 2001). The researchers develop questions that they would like to obtain from each research report. Generally, the goal of coding is to describe the studies used in the meta-analysis and to represent qualitatively important dimensions of studies in data form (such as the research design and theoretically important variables that might affect the direction and/or strength of the relations observed in studies). Researchers will also code information related to the study's findings (e.g., sample size and effect size). Lipsey (2009) discusses how synthesists can go about identifying study features that might influence study outcomes.

Screening and coding are activities that are prone to human error, and as such, steps should be taken to increase the reliability and validity of the judgments made. Best practices in this regard are as follows. First, the individuals doing the screening and coding should be trained, and these individuals should meet regularly to discuss problems encountered and their potential solutions. Part of the goal of both the training and the ongoing meetings is to help coders develop and maintain normative understandings of the questions they are trying to answer. In addition, in most cases both the screening and coding should be done by at least two individuals who work independently. While a good reliability estimate requires more coders than most projects can afford (six coders is probably a bare minimum), systematic reviewers often used two independent coders and report their percentage agreement on key variables, and have the coders reconcile their disagreements (a third coder can be appealed to if the two coders cannot resolve their differences). Finally, the questions used to screen and to code studies should require as little inference as possible on the part of the individuals doing the work. Often this is best accomplished by (1) operationally defining key terms and (2) breaking complex judgments into several smaller, simpler questions. For example, asking coders to rate 'Study Quality' is almost certain to result in an unacceptably high rate of coder disagreement. As such, it is better to break this question into several smaller questions.

Judging Study Quality

Empirical studies vary in terms of the rigor with which they are conducted, and the quality of the studies comprising a systematic review can have an impact on the validity of conclusions arising from that synthesis. Therefore systematic reviewers have to pay close attention to issues related to study quality. Unfortunately, two intuitive and relatively easy to implement strategies turn out to be unhelpful. As mentioned, asking study coders to rate 'study quality' is likely to result in coder disagreement. The reason for this is that coders can differ in terms of the dimensions that they think are related to study quality, and even when they agree on the dimensions, they can disagree about the relative importance of any particular dimension.

Another appealing, simple, and ultimately unhelpful strategy is to use a study quality scale. A review of these instruments is beyond the scope of this article, but unfortunately quality scales have little to recommend them. They tend to (1) be insufficiently operational, (2) lack an empirical basis for the quality dimensions, and (3) use overall quality scores that are composed of several unrelated dimensions. As a result, quality scores tend to lack evidence of validity, and have performed poorly in empirical tests (e.g., see Jüni et al., 1999; see Valentine and Cooper, 2008; for a more thorough review of the issues involved in creating a quality scale). The lack of an empirical basis for the quality dimensions assessed is a key limitation. One of the reasons for this limitation is that what constitutes 'quality' is in fact highly dependent on the context of the research question (Valentine, 2009). This means that systematic reviewers need to think deeply and carefully about how various study quality dimensions might come into play for their review. As an example, attrition (i.e., the loss of participants from a study) is generally viewed as being problematic, and many study quality scales assess it. However, Valentine and McHugh (2007) demonstrated that in studies of educational processes conducted in classrooms with young children, typical levels of attrition might not be problematic at all. They reasoned that in many cases, students might not actually realize that they were in a study, and that attrition might therefore be related to process that are functionally random (e.g., children who happen to be ill on the day the posttest is given). Although this seems fairly obvious in retrospect, most quality scales are not constructed in a way that recognizes different study contexts might change the importance of study quality indicators. It is therefore critical that scholars undertaking a systematic review think carefully about the important study quality indicators for their research question and to code these for every study.

Summary of Systematic Reviewing

In conducting a systematic review, researchers move away from anecdote, the results of single studies, and the results of

incomplete collections of studies and instead approach a well-defined research question by attempting to assemble a collection of studies that strongly resembles the totality of the relevant research literature. Extensive steps are taken to obtain as much of the evidence as possible. Studies are screened by at least two trained individuals working independently. Information relating to the study's background, context, quality, and effects is then coded again by at least two individuals working independently.

Systematic reviewers next need to decide whether and how they will synthesize the results of the studies they have uncovered. The decision about whether or not to synthesize studies is an important one. While the minimum number of studies needed for a synthesis is the classical statistical tradition of two (Valentine et al., 2010), studies should be highly similar to one another for this exercise to be meaningful in such an information poor environment (Cooper, 2003). However, it is also important to consider the quality of the alternatives and the needs of the audience. Because we believe that most alternatives are poor (e.g., see Valentine et al., 2010) and because readers will often conduct the synthesis on their own if a synthesis is not provided (e.g., see Valentine et al., 2011), we believe that meta-analysis (the topic of the remainder of this article) is often the best option.

Meta-Analysis

The term meta-analysis refers to the statistical analysis portion of a systematic review. As we have seen, systematic reviews collect and synthesize the results of a representative sample of studies on a research question, and utilize transparent and systematic methods to conduct the review. In a systematic review, studies are the unit of analysis; the review focuses on making generalizations about a research question from a representative sample of studies on a given topic. The statistical analysis of those studies uses the techniques of meta-analysis. These techniques are analogous to the statistical analysis of any data such as those used to analyze measures collected from individual students or clients. We will introduce the techniques of meta-analysis using the typical stages of data analysis highlighting the differences necessary when the unit of analysis is the study itself.

Collecting Data from Each Study: The Effect Size

As in a primary study of individual students or clients, we systematically gather measures or assessments of outcomes, such as achievement or depression, which are the focus of the study. In a meta-analysis, we are interested in a measure of the study's outcome. This outcome relates back to the research question of the review, and could focus on the effectiveness of an intervention using experimental methods, or the relationship between two constructs such as achievement and depression. The data we gather from each study is called the effect size. In a review of mentoring programs, we might be interested in whether mentoring improves depressive symptoms. Unfortunately studies in the behavioral and social sciences often use different measures for the same construct, such as the Beck's inventory for depression or the Hamilton Depression Rating scale. Since not all studies use measures on the same scale, we need to gather an effect size from each study that is comparable across studies. The form of the effect size depends on the research question and study design. We will focus on three effect sizes that are most common in the behavioral and social science literature: the standardized mean difference, the odds ratio, and the correlation coefficient.

Measures of the Effectiveness of an Intervention

Systematic reviewers are often interested in understanding the effectiveness of an intervention such as a treatment for depression. Studies examining the effectiveness of an intervention employ an experimental design, in the simplest case comparing a treatment group with a control group. The natural measure of a study's effect for experimental designs is the difference between the treatment and control groups. When the outcome is a continuous measure such as a score on an achievement test or a depression assessment, the effect size used is the standardized mean difference. When the outcome is a dichotomous measure such as the number of high-school graduates in the treatment and control group, the effect size used is the odds ratio. Both measures compare the outcomes between a treatment and a control group.

The standardized mean difference is given by the following formula:

$$d = \frac{\overline{X}_T - \overline{X}_C}{s_p} \qquad [1]$$

where $\overline{X}_T$ and $\overline{X}_C$ are the means for the treatment group and the control group, respectively, on the study outcome of interest, such as an achievement score or depression assessment. The denominator of eqn [1], denoted by s_p is the pooled, sample standard deviation for the outcome measure for the treatment and control groups and is given by

$$s_p = \sqrt{\frac{(n_T - 1)s_T^2 - (n_C - 1)s_C^2}{n_T + n_C - 2}} \qquad [2]$$

where n_T and n_C are the sample sizes for the treatment and control group, and s_T^2 and s_C^2 are the sample variances for the outcomes for the treatment and control group.

Each effect size measure also has an associated standard error. Just as we compute the standard error of a treatment group mean, we also need to compute the standard error of our estimate of the effect size. The standard error of the standardized mean difference within a single study is

$$\mathrm{se}(d) = \sqrt{\frac{n_T + n_C}{n_T n_C} + \frac{(d)^2}{2(n_T + n_C)}} \qquad [3]$$

Note that the standard error of the standardized mean difference depends on the estimate of the effect size and (mostly) the sample size, so that studies with smaller sample sizes have larger standard errors. Because standard errors reflect the precision of the estimate (the smaller the standard error, the greater the precision of the estimate), we prefer estimates with smaller standard errors. In fact, in meta-analysis we weight studies differentially by the inverse of their squared standard errors, as will be demonstrated below.

When the experimental study examining the outcome of a treatment is a count of the number of patients who experience

an event such as graduation, the effect size of interest is the odds ratio. The odds ratio may be less familiar to behavioral and social scientists. To illustrate the odds ratio, let us assume that we have an experiment that collected the following data about the outcomes of a mentoring intervention, where the letters a, b, c, and d indicate the number of mentees in each category:

Experimental group	*Graduated (success)*	*Did not graduate (not successful)*
Treatment	*a*	*b*
Control	*c*	*d*

As can be seen in eqn [4], the odds ratio is literally the odds of success in the treatment group relative to the odds of success in the control group:

$$OR = \frac{a/b}{c/d} = \frac{a \times d}{b \times c} \quad [4]$$

We interpret the odds ratio as the ratio of the odds of treatment group members graduating and the odds of control group members graduating. A typical interpretation of the odds ratio uses the terms success and failure for the two conditions, so that we can say that the odds ratio is the ratio of the odds of success in the treatment group to the odds of success in the control group. Note that an odds ratio equal to 1 indicates that the treatment group members and the control group members have an equal odds of graduating (success). An odds ratio smaller than 1 indicates that treatment group members have a lower odds of not relapsing, and an odds ratio greater than 1 indicates that the treatment group has a higher odds of success than the control group.

One nonoptimal property of the odds ratio is that it ranges from 0 to positive infinity. This scale is not evenly spaced and thus the odds ratio does not have a distribution that allows commonly used statistical methods. Thus, we use the natural logarithm of the odds ratio when doing meta-analysis as given by $LOR = \ln(OR)$. The log odds ratio has a scale centered at 0, indicating equal odds of success for the treatment and control group, and ranges from $-\infty$ to $+\infty$. The standard error of the log odds ratio is given by

$$se(LOR) = \frac{1}{a} + \frac{1}{b} + \frac{1}{c} + \frac{1}{d} \quad [5]$$

Note that like the standardized mean difference, the standard error of the log odds ratio also depends on the sample size, with smaller sample sizes leading to larger standard errors, i.e., less precision in the estimation.

Measuring the Relationship between Two Constructs

We are often interested in understanding the strength and direction of an association between two constructs in a systematic review. For example, we may be interested in understanding the strength of the relationship between depression and self-concept in adolescents, or the association between mentor and mentee reports of relationship quality. In this situation, the natural estimate of the study's effect is the correlation coefficient, usually denoted by r. One problem with the correlation coefficient is similar to the problem with the odds ratio, the scale of measurement of r. As we know, the correlation coefficient ranges from -1.0 to 1.0 and thus has properties that do not allow the application of commonly used statistical methods. In meta-analysis, we use a transformation of the correlation coefficient, Fisher's z-transformation, given by

$$z = 0.51n\left(\frac{1+r}{1-r}\right) \quad [6]$$

where we are again taking the natural logarithm of a quantity as we did in the log odds ratio. The standard error of Fisher's z-transformation is

$$se(z) = \sqrt{\frac{1}{n-3}} \quad [7]$$

where n is the sample size in the study. As in all of the effect sizes discussed here, the standard error of Fisher's z-transformation also depends on the sample size, with smaller studies having larger standard errors.

Other Measures of Effect Size

Several other types of effect sizes may be relevant to reviewers. For example, if all the studies use the same measure, a reviewer might want to use the unstandardized mean as the effect size. Another area of interest for reviewers of observational studies is the synthesis of the results from regression studies. Researchers in school psychology and special education are also interested in the synthesis of studies that use single case designs. Methodological research is continuing in a number of these areas (references). In addition, reviewers might find that primary studies do not always provide the summary statistics needed to compute an effect size. There are a number of web-based effect size calculators that can assist reviewers in computing the most common effect sizes from a variety of different summary statistics.

Analyzing Effect Sizes across a Set of Studies

The first step in any statistical analysis centers on understanding the distribution of the observed measures by computing the mean and variance of a variable, and examining a graph of its distribution. In a meta-analysis, we are interested in examining the mean and spread of the effect sizes across studies. We are also interested in understanding how much effect sizes vary across studies, and if that variation is related to differences in the studies' methods, samples, or treatments. Thus, the stages of a meta-analysis conform to that of a typical statistical analysis for primary studies.

In a meta-analysis, however, we need to use methods adapted to the nature of effect sizes. We illustrated above that the standard errors of the study-level effect size depends on the sample size. To compute a mean effect size across studies, we need to take the differences across studies in their sample size, and more specifically in their standard errors of their estimates of effect size into account. Thus, we need to compute a weighted mean effect size across all studies. Imagine that we need to obtain the mean number of times that mentors and mentees met in a month completed across three different agencies. However, different numbers of mentors volunteer at

each agency. We would not want to take the mean number of meetings from each agency, add them up, and divide by three, as this 'average' would not take into account the fact that we might have 50% of the mentors volunteering at agency 1, 35% volunteering at agency 2, and the remaining 15% volunteering at agency 3. Instead, we would weight each agency mean by the proportion of mentors who volunteer at that agency.

In a similar way, we compute the weighted mean effect size across all studies, using the inverse of the standard error of the effect size as the weight. If we denote $w_i = 1/se(ES_i)$ for study i where ES_i is our effect size, we would compute our overall weighted mean effect size across $i = 1, \ldots, k$ studies as

$$\overline{ES} = \frac{\sum_{i=1}^{k} ES_i w_i}{\sum_{i=1}^{k} w_i} \quad [8]$$

The standard error of the mean effect size is given by

$$SE_{\overline{ES}} = \frac{1}{\sum_{i=1}^{k} w_i} \quad [9]$$

Given the standard error and the effect size, we can examine the 95% confidence interval around the overall effect size as

$$95\%CI : \left[\overline{ES} - 1.96SE_{\overline{ES}}, \overline{ES} + 1.96SE_{\overline{ES}}\right] \quad [10]$$

If the 95% confidence interval does not include 0, then the overall mean effect size is statistically significant.

Examining Heterogeneity of Effect Sizes

As is the case in any data analysis, the mean effect size only gives a reviewer a sense of the center of the distribution of effect sizes. We also need to understand how much the effect sizes vary across studies. If we are interested in the effectiveness of a treatment, we want to know not only if the average treatment effect is positive, we also want to know if that treatment effect varies a little or a lot. It could be that the average treatment effect may be positive, but there also may be several studies that find no effect of the treatment or a harmful effect. We examine the variation among effect sizes by computing measures of homogeneity. One test of homogeneity, designated by Q, tests whether the variation across effect sizes in a set of studies is greater than we would expect due to sampling error, i.e., due to the fact that each study uses an independent and different sample of participants. The formal definition of the Q test of homogeneity is given by

$$Q = \sum_{i=1}^{k} w_i \left(ES_i - \overline{ES}\right)^2 \quad [11]$$

Note that the computation of Q includes the difference between the effect size from each study i, and the mean effect size, weighted by the inverse of the standard error of the effect sizes. Thus, large values of Q indicate more variation of study effect sizes from the mean effect size. We compare the obtained value of Q to a chi-square distribution with $k - 1$ (k equal to the number of studies) degrees of freedom. The null hypothesis of Q is that the effect sizes are homogeneous; large values of Q lead to the rejection of the null and a conclusion that the effect sizes are not estimating a common mean effect size.

A second measure of the homogeneity of effect sizes is the index I^2. The index I^2 gives us the proportion or percentage of variation in the effect sizes that is not associated with sampling error, or differences in the samples of individuals in the study. We compute I^2 as

$$I^2 = \left(\frac{Q - k - 1}{Q}\right) \times 100\% \quad [12]$$

The index I^2 gives a reviewer a sense of how much of the variation across studies needs to be explored. For example, a small value of I^2 such as 20% indicates that only 20% of the variation in effect sizes is not due to sampling error. In contrast, a value of I^2 such as 75% indicates that much of the variation in effect size is not related to differences between the samples of participants and must be due to other differences among studies.

In a situation with a large I^2 and a statistically significant Q value, a reviewer should be hesitant to use the overall mean effect size as an indicator of the 'average' treatment effect or the 'average' strength of the relationship between two constructs. In the presence of heterogeneity among effect sizes, the reviewer should explore the possible reasons for that heterogeneity through the use of moderator analyses, a topic that will be covered below.

Moderator Analyses in Meta-Analysis

When a reviewer finds a large value of I^2 or a significant value of Q, these results are a signal that the studies may not be estimating a common effect size, and/or that the studies differ for reasons beyond the fact that they use different samples of participants. Reviewers can explore the heterogeneity across studies using models that are analogous to Analysis of Variance (ANOVA) and regression. Often a reviewer is most interested in potential variation among studies in their estimates of a treatment effect or the strength of a relationship between two constructs. For example, a mentoring intervention may have differential effects for boys and girls, or the effectiveness of mentoring may depend on how often the mentor meets with the mentee. Any variations among studies in the genders of participants or in the frequency of meetings could be associated with differences in estimates of the study's effect size. As we have seen, during coding reviewers will have gathered not only information about effect sizes from studies during the data collection phase of a systematic review, but will also have coded information about the studies' methods, participants, measures, and other characteristics. All of these study characteristics can be used as predictors in models that explore the potential moderators of effect size.

We use a statistical analysis comparable to ANOVA when we have a moderator variable that has a small number of categories. For example, we may want to compare the effect sizes in studies in which the typical relationship quality was rated as high to studies in which typical relationship quality was rated as average. The analysis context is similar to a one-way ANOVA where we want to compare the mean of one group (in this case, studies with typical relationship quality rated as high) versus another group (studies with typical relationship quality rated as average). As in ANOVA, the variation among effect sizes as represented by the Q statistic can be separated into two pieces, one associated with the variation among the group means, and one that is the variation within groups just as we compute the between and within components of variance in an ANOVA. Categorical models of effect size will compare the mean effect

size within each group using the statistic $Q_{between}$, similar in interpretation to an F-test for between groups. In addition, the within-group component of variation, Q_{within}, can be computed and is a measure of the homogeneity within groups in their estimates of effect size. Note that effect sizes have standard errors that depend on the sample size in the study, and thus do not share a common variance. Techniques of ANOVA assume heteroscedasticity, that the groups share a common within-group variance. The computations of the Q statistics in meta-analysis differ from the usual ANOVA calculations in that the inverse of the standard error of the effect sizes are used in a weighted analysis.

When the moderator variables of interest are continuous, such as the average age of the mentees in the sample, or when we have multiple variables of interest, regression techniques, commonly called meta-regression, can be used to explore the associations between study characteristics and effect size. In meta-analysis, we again use weighted regression techniques since our effect sizes violate the assumption of heteroscedasticity.

One caution with moderator analyses in meta-analysis concerns the types of generalizations that are possible. By definition, models of effect size in meta-analysis are observational studies. Reviewers do not have control over the types of studies that exist in the literature, and thus cannot randomly assign studies to different conditions as we can in a randomized trial. Given that a meta-analysis is an observational study design, we can only talk about associations between study characteristics and variation in study effects. In addition, the relationships we may discover between study characteristics and effect sizes are at the level of the study, and cannot be generalized to any other level. For example, if we find that studies with larger effect sizes tend to have more boys included in the study, this finding does not mean that the treatment is more effective for boys than girls. Our generalization would be subject to an ecological bias – assuming that a finding at the level of the study would hold at the level of the individual.

Random Effects Models of Effect Size

Up to this point, our presentation of meta-analysis has assumed what we call a fixed effect model, that the differences among studies in their effect size estimates is due only to sampling error and observed differences among study methods and characteristics. However, the more commonly used framework for meta-analysis is to assume a random effect model. In a random effects model, the reviewer assumes that the studies we have gathered for our systematic review are sampled from a population of studies and thus effect size estimates are essentially a random sample from an unknown population of effect sizes. Practically speaking, in a random effects model, the reviewer assumes that there may be underlying variation among study effect sizes that is unknowable, or just due to random variation that cannot be accounted for by differences among study methods.

In random effects models, we estimate not only the mean effect size, which represents the mean of the unknown population of effect sizes, but also the variance of that population, denoted by τ^2 and called the random effects variance component. The effect size estimated from each study has a standard error that is the sum of two components, the variance component, τ^2, and the usual sampling variance we detailed in our discussion above. Thus, the standard error for the standardized mean difference for a study is $\tau^2 + se(d)$ given in eqn [3]. Each study's estimate of the effect size will have a larger variance in a random effects model. In addition, adding τ^2 to each study's estimate of the standard error serves to make the weights (the inverse of the standard error of the effect sizes) more equal to each other (the ranks of the weights remain the same however, so the study with the most weight in the fixed effect analysis also has the most weight in the random effects analysis). The analysis of the overall mean effect size using random effects models focuses on estimating both the overall mean effect (using the inverse of the random effects standard errors as weights), and the variance component, τ^2. Confidence intervals around the overall mean effect size use the value of the variance component, and we test the homogeneity of the effect sizes through the statistical test of whether τ^2 is statistically different from zero.

Future Directions for Meta-Analysis

New meta-analysis work centers on two areas: analysis methods for study designs and research questions not addressed by current meta-analysis techniques, and methodological research on more-efficient and less-biased methods for computing effect size estimates and models of effect sizes.

Diagnostic Test Accuracy

Researchers in medicine have been developing methods for examining the accuracy of diagnostic tests. Often, the 'gold standard' test of a particular diagnosis is expensive or invasive, such as using tissue biopsy to diagnose cancer. Newer and less-invasive diagnosis procedures are often suggested, and researchers are interested in how accurate these tests are in comparison to the old gold standard test. There are a series of methods to synthesize the results of studies that compare the accuracy of a newer test to the gold standard for diagnosing a condition. Researchers in the social and behavioral sciences have not yet applied these methods for psychological or other types of tests. There are a number of areas, however, where students are diagnosed with a particular condition or tests are used to predict a student's later performance. The literature in these areas could be synthesized using techniques developed in medicine for examining diagnostic test accuracy.

Bayesian Meta-Analysis

As discussed earlier, random effects models of effect size have become the most common method for synthesizing a set of effect sizes. One difficulty, however, is the computation of the variance component, τ^2. There is much research on the drawbacks of our usual methods for estimating the variance component and the assumptions we make in using the current methods for computation. Bayesian methods, in general, have become more common in statistical analyses given innovations in computing and more readily available computer programs to conduct these analyses. In a Bayesian analysis, we are concerned with estimating the joint distribution of parameters of interest – in meta-analysis, the overall mean effect size, the effect sizes for each study, and the variance component – given the data we have in hand. More formally, we are interested in estimating the joint posterior distribution of the parameters of

interest in meta-analysis given the data. Bayesian analysis allows us to make probability statements about our parameters of interest, stating, for example, that the overall mean effect size has a 95% probability of lying between two points (this is how people often interpret 95% confidence intervals arising from more classical statistical traditions, but that interpretation is not strictly correct). In addition, Bayesian methods allow the use of more complex distributions of parameters so that we do not have to make simplifying assumptions such as normality that are not realistic. Bayesian methods are used more extensively in medicine especially in the synthesis of studies in genetics, and are likely to allow social and behavioral researchers more flexibility in applying more complex models of effect sizes.

EDITOR IN CHIEF BIOGRAPHY

James D. Wright received his bachelor's degree in philosophy from Purdue University in 1969, a master's degree in sociology from the University of Wisconsin in 1970, and his PhD in sociology from Wisconsin in 1973. His first academic appointment was at the University of Massachusetts, Amherst, where he was promoted to Associate Professor in 1976 and to Full Professor in 1979. Most of his 15 years at Massachusetts were spent as Director, Associate Director, or Director of Research in the Social and Demographic Institute.

Wright left Massachusetts for Tulane University in New Orleans in 1988 where he served as the Charles and Leo Favrot Professor of Human Relations in Tulane's Department of Sociology. He also enjoyed a courtesy appointment in the Tulane School of Public Health, Department of Biostatistics and Epidemiology. He left Tulane in 2001 to become the Provost's Distinguished Research Professor of Sociology at the University of Central Florida. In 2003, he was named as the Director of the University's Institute for Social and Behavioral Sciences and in 2013, was designated as a UCF Pegasus Professor, the University's highest faculty honor.

Wright was the Editor in Chief of the scholarly journal *Social Science Research* from 1978 until 2014. His previous editing experience also includes a 20-year stint as editor of the Aldine de Gruyter book series *Social Institutions and Social Change*, two editions of the *Handbook of Survey Research* (Academic Press, 1983; Emerald Publishing, 2010), and service on the editorial boards of numerous journals. He is the author of 21 books and scholarly monographs on topics ranging from homelessness to research methods to NASCAR, and he has published more than 300 journal articles, book chapters, reviews, essays, and polemics. Wright lives with his wife Christine Stewart and their multiple dogs and cats in Winter Springs, Florida, where in his spare time he likes to cook fancy meals for large crowds.

PREFACE TO THE FIRST EDITION

Large and ambitious works such as the present Encyclopedia depend on countless instances of input, cooperation, and contextual support. Therefore, the editors in chief would like to express their gratitude to several institutions and individuals. Our most general thanks go to our respective home institutions, the Center for Advanced Study in the Behavioral Sciences, Stanford, and the Max Planck Institute for Human Development, Berlin. We are certain that without the effective infrastructures of these institutions and the rich collegial networks and intellectual climate they provide, implementing this Encyclopedia in such a short amount of time would not have been possible. In this context, we also need to mention that due to the administrative budgets provided to the editors in chief by the publisher, the financial strains on our home institutions were minimal. Such a situation may be a rarity in the modern world of scientific publishing where publishers often press scholars and institutions into taking on larger and larger shares of the publication enterprise.

Aside from the more than 4000 authors, our deepest thanks goes to the editors of the 39 sections, to whom we delegated many decisions at various stages, who were primarily responsible for developing the lists of articles and authors, and who stood as the main gatekeepers of scientific quality for the entries in their sections. As a group, the section editors displayed remarkable energy, intelligence, and tolerance for the inevitable frustrations of tending large numbers of authors over a long period of time. Because of the brevity of the acknowledgment of the main editorial coproducers here, we alert the reader to the list published as part of the front matter and the description of their extensive work we offer in the Introduction. We would also like to mention that one of our highly esteemed section editors, Franz Weinert, died unexpectedly during the last phases of his editorial work. For people who had the pleasure of knowing Franz Weinert, it comes as no surprise that he completed his editorial duties without ever complaining about the difficult health conditions he was facing. He was a gentleman and a distinguished scholar.

The International Advisors also gave wise counsel on several designated occasions, and a number of these scholars represented on the International Advisory Board took more initiative — always helpful — than we had originally asked. The International Advisory Board was particularly helpful in the process of choosing section editors. Some of its members assisted us ably as we attempted to make the Encyclopedia as international as possible and also in dealing with special problems that are part of a large project with close timelines. Thus, we remember a few occasions where members of the International Advisory Board helped us with their substantive and social competence to deal with matters of editorial disagreements. Because of the overall quality, collaborative spirit, and professional responsibility of our section editors, these events were rare indeed, but dealing with them required masterful and accelerated input. We appreciate the collegiality that members of the Board displayed when called upon in these special circumstances.

In addition, and as described in the Introduction, there was a host of esteemed colleagues who gave us advice on numerous questions such as author and editor selection, organizational matters, topics for entries, content and quality of selected articles, substantive and methodological niches to be covered, as well as last-minute author replacements. The number of such individuals is large indeed, and most likely, significantly larger than the list presented below. There were too many short, but nevertheless significant collaborative encounters that we likely did not deposit into our long-term memory or written documentation. We apologize for such oversights.

In this spirit, we appreciate the advice given in the three planning meetings in Stanford, Uppsala, and Dölln/Berlin by the following scholars: Peter Behrens, Burton Clark, Gordon Clark, Lorraine Daston, Meinolf Dierkes, Jean-Emile Gombert, Torsten Husén, Gérard Jorland, Ali Kazancigil, Wolfgang Klein, Gardner Lindzey, Renate

Mayntz, Andrew Pettigrew, Denis Phillips, Marc Richelle, Ursula M. Staudinger, Piotr Sztompka, Eskil Wadensjö, Björn Wittrock, and Robert Zajonc.

We would like to extend special thanks to Laura Stoker, who pinch-hit for Nelson Polsby (section editor for Political Science) who was unable to attend the meeting of section editors in April 1998; and to Linda Woodhead, Senior Lecturer in Religious Studies, Lancaster University, who assisted David Martin with editorial work at all phases for the section on Religious Studies.

We also acknowledge the help of scholars who advised Smelser and Baltes at the stage of pulling together the entry lists, proposing authors, and occasionally reviewing the content and quality of articles submitted.

Smelser thanks: Jeffrey Banks, Peter Bickel, Edgar Borgatta, Charles Camic, Jennifer Chatman, Jean Cohen, Michael Dear, Pierre Ducrey, Eckart Ehlers, Sylvie Faucheux, Steven Guteman, Frank Furstenberg, Helga Haftendorn, Peter Katzenstein, David Laibson, Stephan Lauritzen, Douglas McAdam, Eleanor Maccoby, Phyllis Mack, Cora Marrett, Douglas Massey, Donald Melnick, Harvey Molotch, Lincoln Moses, James Peacock, Trond Petersen, Andrew Pettigrew, Alejandro Portes, Matilda Riley, István Rév, John Roberts, Dorothy Ross, Rob Sampson, Fritz Scharpf, Melvin Seeman, James Short, Fritz Stern, Carol Swain, Ann Swidler, Ken'ichi Tominaga, Charles Tilly, Wolfgang van den Daele, Sidney Verba, Margaret Weir, Thomas Weisner, and Jennifer Wolch.

Baltes is very grateful to: Nancy Andreasen, Gerhard Arminger, André-Jean Arnaud, Jens Asendorpf, Jan Assmann, Margret Baltes (deceased), Jürgen Baumert, Peter Behrens, Manfred Bierwisch, Niels Birbaumer, Peter Bloßfeld, Walter Borman, Robert F. Boruch, Mark Bouton, Michael Bratmann, David Buss, Shelley Chaiken, Lorraine Daston, Juan Delius, Marvin Dunnette, Georg Elwert, Helmut Fend, Hans Fischer, Peter Frensch, Alexandra M. Freund, Dieter Frey, Jochen Frowein, Gerd Gigerenzer, Snait Gissis, Peter Gollwitzer, Ian G. Gotlib, David Gyori, Heinz Häfner, Helga Haftendorn, Giyoo Hatano, Adrienne Héritier, Theo Herrmann, Otfried Höffe, Ludger Honnefelder, Paul Hoyningen-Huene, James Huang, Günther Kaiser, Heidi Keller, Martina Kessel, Gábor Klaniczay, Wolf-Hagen Krauth, Achim Leschinsky, Karen Li, Shu-Chen Li, Ulman Lindenberger, Elizabeth Loftus, Gerd Lüer, Ingrid Lunt, Hans J. Markowitsch, Laura Martignon, Randolf Menzel, Dietmar Mieth, Susan Mineka, Setsuo Miyazawa, John R. Nesselroade, Claus Offe, Vimla Patel, Meinrad Perrez, Rosa Lynn Pinkus, Robert Plomin, Neville Postlethwaite, Thomas Rentsch, István Rév, Peter Roeder, Richard Rorty, Hubert Rottleuthner, Peter Schäfer, Heinz Schuler, Norbert Schwarz, Richard J. Shavelson, Joan E. Sieber, Burton Singer, Wolf Singer, Edward Smith, Hans Spada, Günter Spur, Rolf Steyer, Michael Stolleis, José Juan Toharia, LeRoy B. Walters, Elke U. Weber, Peter Weingart, and Reiner Wimmer.

There was one more group that played a special role in the editorial review (see also Introduction). Baltes was assisted by a team of colleagues who provided expert input to the section editors and to him during final review: Gregor Bachmann, Alexandra M. Freund, Judith Glück, Wolfgang Klein, Olaf Köller, Shu-Chen Li, Ulman Lindenberger, Ursula M. Staudinger, and Christine Windbichler. Their expertise in helping us to ensure quality is gratefully acknowledged.

The day-to-day organizational work of the editors in chief occurred at their respective research centers — the Center for Advanced Study in the Behavioral Sciences and the Max Planck Institute for Human Development in Berlin. Smelser singles out Julie Schumacher, his main assistant in the project, for her organization of the meeting of section editors, and her superb coordination of the flow of correspondence and manuscripts over several years. She remained firm when the rest of us were faltering, and displayed the greatest efficiency, intelligence, and good cheer. Smelser also relied on periodic help from Leslie Lindzey, Kathleen Much, Jane Kolmodin, and Anne Carpinetti. Michelle Williams of the University of California, Berkeley, served as his main editorial assistant for nearly 2 years, going over all entry manuscripts from the standpoint of readability, and carrying a great part of the cross-referencing work; her judgment was always the best, and Smelser is forever indebted to her.

At the Max Planck Institute for Human Development, and aside from Julia Delius (see below), Baltes expresses his deeply felt thanks to the main secretarial staff in his office (Helga Kaiser, Romy Schlüter, Conor Toomey) who during the preparation of this Encyclopedia took on larger shares of responsibilities for other projects and occasionally helped out when the editorial office was overloaded. More directly involved in the day-to-day operation of the Encyclopedia was Penny Motley, who efficiently functioned as project secretary during the planning phase. During the main phases of the project, it was Yvonne Bennett who was responsible for secretarial and organizational matters. She deserves much applause for her superb and efficient help in the day-to-day running of the editorial office, making sure that all manuscripts and proofs were processed quickly, and also for assisting with the organization of various meetings. Not least, Baltes thanks the administrative office of the Max Planck Institute, and there especially Nina Körner and Karin Marschlich, for their competent work in managing the project budget, as well as Sabine Norfolk who handled most of the numerous fax

transmissions with ever present smiles and friendliness. Finally, in the Berlin editorial office, thanks are also due to Susannah Goss for her excellent work in translating individual articles into English.

Individual section editors wish to thank the following scholars who gave them substantive advice in their work: Richard Abel, Itty Abraham, John Ambler, Karen Anderson, Mitchell Ash, Alan Baddeley, Boris Baltes, Manfred Bierwisch, Michael Bittman, Sophie Bowlby, John Carson, Shelly Chaiken, Roger Chartier, François Chazel, Stewart Clegg, Carol Colby, Philip Converse, James Curran, Jerry Davis, Natalie Z. Davis, Peter Dear, Juan Delius, Michael Dennis, Josh DeWind, Sherry Diamond, Elsa Dixler, Georg Elwert, Howard Erlanger, Drew Faust, Malcolm Feeley, Nancy Folbre, Michael Frese, Angela Friederici, Lawrence Friedman, Bryant Garth; Victor Ginsburgh; Marcial Godoy, Frances Goldscheider, Calvin Goldscheider, John H. Goldthorpe, Reginald Golledge, William Graziano, Stephen Gudeman, Mauro Guillen, Doug Guthrie, John Hagan, Eric Hershberg, Steve Heydemann, Stephen Hilgartner, Judith Howard, William Howell, Jill Jaeger, Bob Kagan, Joe Karaganis, Roger E. Kasperson, Ronald Kassimir, Robert W. Kates, Wolfgang Klein, Hans-Dieter Klingemann, Bert Kritzer, Kay Levine, Steven Lukes, Michael Lynch, Akin Mabogunje, Stuart Macaulay, Donald MacKenzie, David Magnusson, Michael McCann, Sally Merry, Peter Meusburger, Sieglinde Modell, John Monahan, Kevin Moore, Gerda Neyer, Hiroyuki Ninomiya, Jodi O'Brien, Eva Oesterberg, Mark Osiel, James L. Peacock, Susan Phillips, Trevor Pinch, Wolfgang Prinz, Sheri Ranis, Harry Reis, Estevao C. de Rezende Martins, Marc Richelle, Leila Rupp, Gigi Santow, Austin Sarat, Simon Schaffer, Linda Scott, Tim Shallice, Seteney Shami, Ronen Shamir, Susan Silbey, Wolf Singer, Sheila Slaughter, Gerhard Strube, Ursula M. Staudinger, J. Stengers, Stephen M. Stigler, Michael Stolleis, Mark Suchman, Denis Szabo, Verta Taylor, Ashley Timmer, David Trubek, Leslie Ungerleider, Don Van Arsdol, Jakob Vogel, Rita Vörg, Judy Wajcman, Mary Wegner, Wlodzimierz Wesolowski, Steve Wheatley, Björn Wittrock, and Vincent Wright (deceased).

Section editors also thanked the following persons for their research assistance: Pamela Anderson, Susan Augir, Anja Berkes, Chantale Bousquet, Aida Bilalbegović, John Clark, Susanne Dengler, Kathrine Derbyshire, Annie Devinant, Casey B.K. Dominguez, Barbara Dorney, Elizabeth Dowling, Tracey L. Dowdeswell, Carolyn Dymond, Debbie Fitch, Susannah Goss, Verhan Henderson, Andrew Hostetler, Gudrun Klein, Heike Kubisch, Angie Lam, Ellen Lee, Valerie Lenhart, Kay Levine, Allison Lynn, Helena Maravilla, Carol B. Marley, Marion Maruschak, Michael McClelland, Rhonda Moats, Birgit Möller, Katja Neumann, Linda Peterson, Justin Powell, Paul Price, Xandra Rarden, Chris Reiter, Deborah Sadowski, Heidi Schulze, Heidi Sestrich, Keith Smith, Judith Thompson, Karen Varilla, Stuart Vizard, Danelle Winship.

It is difficult to single out one person as especially helpful. Despite the risks involved, we would like to highlight one person (see also Introduction). As shown in the front matter, beginning in the second year of the planning phase, Julia Delius served as our scientific editorial assistant. For our internal process of editorial review and management, Julia Delius was the mastermind of editorial coordination. Her work was simply outstanding.

Finally, we express our thanks to several individuals at Elsevier publishers whose work was both essential and helpful to us throughout. Barbara Barrett started the ball rolling for the entire Encyclopedia project, and was a master at negotiating out the fundamental arrangements at the beginning. Geraldine Billingham, as executive editor, also played an important role in the development of the project, as well as carrying the heavy responsibility for ensuring that all the financial and operational aspects of the project were realized. She executed this work with directness, skill, and tact. Angela Greenwell coordinated the editorial process with dexterity, calmness, and good judgment. Three persons were responsible for monitoring the progress of entries from Elsevier's side: Michael Lax for a time at the beginning; Jayne Harrison, who carried an overwhelming load of manuscripts month after month, and Helen Collins, who was responsible for the equally demanding job of shepherding the manuscripts through the entire production process. Ruth Glynn skillfully and imaginatively masterminded the development of the electronic version within Science Direct. We know how much the success of the Encyclopedia has depended on these individuals and their staffs, and our appreciation and admiration is here recorded.

Our expressions of gratitude and respect for the authors, section editors, reviewers, counselors, and editorial team, however, are not meant to distract from our own responsibilities as editors in chief. Let us hasten to add, therefore, that those whom we acknowledge deserve most of the credit but little of the blame for whatever shortcomings remain.

Neil J. Smelser
Paul B. Baltes
Palo Alto and Berlin
June 2001

INTRODUCTION

Alan Sica's article in this encyclopedia observes, "The urge to systematize and rationalize both common and esoteric knowledge has been strongly and continuously in evidence for at least 2400 years in the West" (Sica, 2015). Sica dates the origins of this urge to Plato's nephew Speusippus, who took up the challenge of Plato's call for an *encyclopedia* (from Greek words meaning 'general education'), and traces the urge though Pliny the Elder, Vincent of Beauvois, Francis Bacon, Denis Diderot, and a great many others. Today, an encyclopedia is simply a self-contained reference work "with two aims: to include up-to-date knowledge about a particular discipline or group of disciplines and to make this knowledge conveniently accessible" (Smelser and Baltes, 2001). Such are the aspirations of the present work.

Histories of the concept of an encyclopedia are widely available and need not occupy us here. Those interested in where the *International Encyclopedia of the Social and Behavioral Sciences* (IESBS) fits into the long history of encyclopedias will do well to consult the Sica article quoted above or the Smelser–Baltes 'Introduction' to the first edition of this work.

This is the second edition (2/e) of the IESBS. Elsewhere, I acknowledge my immense debt to the editors of the first edition, Dr Neil Smelser and Dr Paul Baltes. Without their perspective and template to follow in assembling the second edition, this version would have scarcely been possible. The very thought of an encyclopedia covering *all* the social and behavioral sciences, one that drew on scholars from *all* corners of the globe, is itself so audacious that one would hesitate even to begin without a pretty detailed road map to the terrain.

On the occasion of the publication of Robert E.L. Faris's widely acclaimed *Handbook of Modern Sociology*, Joseph Gittler was moved to ask, "With the plethora of new handbooks, reviews, and compendia in sociology, one wonders whether there is a need for yet another one." That question was posed almost 50 years ago; the ensuing half-century has been marked, as Sica says, by "an avalanche of reference materials the likes of which had never been seen in libraries prior to about 2000." So readers and critics are within their rights to ask: Why a second edition? Why now?

The first edition (1/e) was reviewed in *Contemporary Psychology* as "the largest corpus of knowledge about the social and behavioral sciences in existence" (Park, 2004). According to readily available data sources, IESBS 1/e has been cited nearly 6000 times in subsequent scholarly literature and has an h-index ($h = 24$) that would be the envy of many full professors. Citations are only one measure of impact, of course, and probably not the most important measure for a basic reference work intended more for students and a general audience than for practicing professionals. In addition to the thousands of scholarly citations, items from IESBS 1/e were 'hit' almost two *million* times on Science Direct between online publication in November 2002 and August 2014 — two million instances where IESBS 1/e was likely consulted as a basic reference source, to get quickly up to speed in a new area of research or to provide background for a paper or project, or just to satisfy a reader's curiosity. The first edition, in short, emerged soon after publication as a go-to reference work throughout the social and behavioral sciences. Michael Shanahan referred to the first edition as "the atomic bomb of reference works." It was thus an easy conclusion that the work had sufficient value to keep it alive and current.

In reading selected articles from the first edition, however, I was taken aback by how much and how quickly they had aged. The first articles I looked at were those pertinent to my own areas of research and in nearly every case, there was important recent work that I felt needed to be discussed. With the assistance of colleagues in other areas of the social and behavioral sciences, it became obvious that this was a general problem. To be sure, much of the material in 1/e has enduring value; indeed, roughly half the articles in 2/e are updated and revised items from the first edition. Still, it is sobering to realize just how quickly the frontiers of social science

knowledge shift and thus how quickly a basic reference source becomes dated. I am certain there are articles in the current edition that are already in need of some updating.

Smelser and Baltes enumerated six criteria that guided their decisions about what to include and what to leave out. The criteria are as follows:

1. secure knowledge, realizing that security of knowledge is a dynamic and relative term,
2. knowledge with balance and comprehensiveness,
3. knowledge that is integrative rather than fragmented,
4. knowledge that places the evidence into historical and theoretical context,
5. knowledge that highlights connections between topics and fields, and
6. knowledge that combines, where possible, theory and practice.

I would like to say I have followed these same criteria in determining the content of 2/e, but all six criteria have proved problematic in one or another way and thus deserve some comment in light of the present work:

1. What is secure knowledge today is apt to be recognized as wrong tomorrow. Many of our requests for updates to 1/e articles generated some response to the effect, "All of this is completely obsolete. We need to write a new entry from scratch." One would expect this to be true of areas of research such as behavioral genetics, say, or cognitive neuroscience or other fast-moving scientific fields, but it also turns out to be true of archaeology, history, and philosophy. The leading edge of research in *every* discipline threatens received wisdom; those who content themselves with received wisdom ('secure knowledge') will quickly find themselves behind the times. So our charge to authors was to focus less on the 'secure knowledge' in their respective fields and more on the cutting edge — the new perspectives, methods, findings, and issues that will animate social and behavioral science research in the coming decade.
2. Throughout the social sciences, the distinction between theory and ideology is sometimes difficult to discern, and so too the distinction between applied research and community or political activism. We need not invoke Max Weber's conclusions about the impossibility of a truly value-free social science to understand that ideological undertones and political preferences can often be detected in social science research work; sometimes, they are quite explicit. Nor is it much of a surprise to learn that many social scientists struggle, not always successfully, to distinguish between what they want the world to be and what the world in fact is. Such struggles are part of the process by which knowledge develops and are thus in evidence in many of the 2/e articles. It would be unwise to enforce by editorial fiat a consensus on issues that the social sciences themselves have yet to resolve.
3. The fragmentation of knowledge *across* disciplines is far more serious that the fragmentation of knowledge *within* them, although the latter is a problem as well. Many well-informed sociologists, for example, take pride in reading widely and can speak with some authority about what is going on in the field, even in areas of sociology that do not directly concern them. I assume this is also true of the other social and behavioral science disciplines and areas. But rare is the sociologist who is cognizant of work being done, say, in social geography *even when*, as is often the case, the fundamental problems, theoretical issues, and methodological approaches are similar. This is a widespread problem across the disciplines: The evolutionary psychologists do not know as much as they should about what the anthropologists are doing; the economists ignore a lot of pertinent work in sociology and political science; etc. For better or worse, disciplinary differentiation is an inherent element in the process of knowledge development and discovery, so this is a reality to be faced, not a problem to be solved. We dealt with this reality mainly in two ways: (1) Authors were encouraged wherever possible to think across rather than strictly within their disciplines. (2) Calling relevant work done in other disciplines to the reader's attention was a guiding principle for the choice of cross-references for each article.
4. Social-constructionist theories of knowledge would argue that knowledge does not become knowledge until it is placed in historical, cultural, social, political, and theoretical context. As put very simply and succinctly in the opening line of the famous text by Berger and Luckmann, "reality is socially constructed" (1966: 1). This is no less true of social science knowledge than knowledge in any other realm. Unfortunately, a great deal of what we think of as social science knowledge is based on biased samples of WEIRD people — that is, Western, Educated, Industrialized, Rich, and Democratic (Henrich et al., 2010). (The same point has, of course, been made by many others.) The WEIRD, thus defined, represent a rather exotic minority group judged by world standards, and the challenge for IESBS 2/e was therefore twofold: (1) to recruit non-WEIRD editors and authors where possible; and (2) to persuade all authors to incorporate comparative, cross-cultural, and

international themes and perspectives wherever it was possible to do so. This effort was more effective in some sections than in others. Moving away from nation-specific literature, themes, and results to a truly *international* (the I in IESBS) account of the social and behavioral sciences was an ever-present *desideratum* in my discussions with editors and authors.

Alas, an emphasis on cross-culturalism often brings to light that everything, or nearly everything, seems to vary by culture, subgroup, ethnicity or nation, and at that point the question arises whether social science generalization is even possible. Are there universals that cross all social groupings? Or does social science dissolve into a mist of group-specific particularities that adduce no general principles? That hardly seems desirable. Yet myopic and ethnocentric fixations on one's own society or culture are scarcely to be encouraged either.

The worst offenders in this regard tend to be social scientists from the USA (and from the West more generally), who, of course, also comprise the largest share of editors and authors for IESBS 2/e. True, as with greenhouse gases, the USA (and the West) also produce the largest share of the world's science, social and otherwise, and so it is inevitable that they also represent the largest share of IESBS 2/e contributors. The Swedish social anthropologist Ulf Hannerz wrote about this very issue in his marvelous essay, "Editing Anthropology" (Hannerz, 2010). Hannerz quotes a Canadian anthropologist who said of the "neighborly presence" of US anthropology that it was like being "in bed with the elephant." The same is true of most or all of the disciplines covered in this work. But then in a passage remarkable for both its insight and its generosity, Hannerz remarks, "No doubt tensions and conflicts may arise out of this situation, but perhaps it is better to understand that the elephant cannot help being an elephant, and that it makes sense for it, in its habitat, to behave in elephantine ways. A well-trained elephant, too, can do a lot of good, such as in carrying heavy loads." So if the elephant that is Western social and behavioral science has been pressed to carry the heavier load in these pages, that is, the price to be paid for being an elephant in the first place.

The larger issue here is that the social and behavioral sciences, which were largely birthed in the West, in Europe and the United States, mainly address a trans-Atlantic scientific dialogue, a dialogue that is carried out almost exclusively in English. Indeed, throughout much of the world, a scientist's stature is indexed in part by his or her success in publishing in English. Publications in the native language are simply *assumed* to be inferior. The main exceptions, tellingly, are French and German social scientists whose native-language publications are valorized. A Dutch or Portuguese or Hungarian social scientist who only published in the native language would be seriously punished in merit and tenure reviews. Elsevier's citation database Scopus *requires* English-language abstracts before a journal will even be considered for inclusion. And English (with American spellings) is likewise the official language of this encyclopedia. No resources were made available to get articles submitted in other languages translated (although several such articles were submitted). Inevitably, this biases the encyclopedia's coverage in favor of social science addressed to the trans-Atlantic dialogue. Consequently, a great deal of excellent social science published in Spanish, or Mandarin, or Farsi, or any of the other world languages, is overlooked.

That said, steps were taken to improve the internationalism of the encyclopedia's coverage throughout the 4 years of its development. To begin, I sought area and section editors from around the globe and urged them whenever possible to seek international (vs strictly Western) authors. Articles were often returned to their authors with explicit instructions to add international coverage. And when all efforts failed and we ended up with articles that were unmistakably restricted to a single nation in their coverage (frequently but not always, this was the US), I indicated the national focus in the article subtitle. Still, a great deal more WEIRD social and behavioral science remains in these pages than would be desirable in an *international* encyclopedia. In a later section, I give the national breakdown of everyone involved in this project.

5. An encyclopedia that "highlights connections between topics and fields" is easier to envision than to accomplish. Criterion (3) above speaks to the disciplinary fragmentation of our social science knowledge. William Easterly, the NYU economist, has written about the 'tyranny of experts' but the tyranny of the disciplines is an equal problem, a tyranny sanctified by the very academic structure of the modern university, where the separate and often warring colleges are each comprised of assorted departments, the latter representing basic academic disciplines. Interdisciplinary programs are almost invariably relegated to various centers, institutes, or specialized research laboratories — in short, to the periphery of the university's power structure. And while everyone *says* they want to encourage multi- and interdisciplinarity, very little is done to make that happen. Instead, departments remain as the fundamental unit of academic organization.

   Hortatory admonitions to editors and authors have made IESBS 2/e somewhat more interdisciplinary than its several predecessors, but in the end, the disciplinary emphasis in many of our articles would be hard

to overlook. Still, there are many sections of the work that were clearly developed with interdisciplinarity in mind and in which one finds interdisciplinary social science at its current best: environmental and ecological sciences; health; life course; sexuality; GLBT studies; public policy; evolutionary sciences; war, peace, violence, and conflict; and genetics, behavior, history, and society are a few sections that come immediately to mind.

I am particularly pleased with the extensive coverage given in 2/e to the interactions between the biological and social sciences. Harry Whitaker once remarked in a private e-mail that "we are all witnesses to the marriage of biology and the social sciences." Many of the articles found here are offspring of that marriage. And those articles leave little doubt that the future offspring of this marriage will be among the most exciting and insightful social science products of the coming decade.

The social sciences once resisted everything biological as rank reductionism; in addition, the social scientists have always feared that a mature and complete biology would eventually drive us out of business. Articles included in IESBS 2/e make it clear that 'nature' versus 'nurture' was the wrong question from the very beginning, that what we need to understand is how biological inheritance and social and cultural forces *interact* to produce individual and collective outcomes. This is where a lot of the interesting action in the social sciences is going to be in the coming years.

6. The coverage of the practical or applied sides of the various disciplines has been increased in this edition, so the applied content of 2/e certainly exceeds that of its predecessor. New to this edition is the entire section on applied social and behavioral sciences; also new is our large section on social work and the separate section on applied, industrial and organizational psychology. But as Sara Strickhouser and I say in our article on the history of applied social research, "The history of 'applied social science' is indeed the history of the social sciences themselves" (Strickhouser and Wright, 2015). All of the social sciences in their modern form were birthed in the post-Enlightenment effort to understand why people, their institutions and society as a whole were as they were — why greed was more visible than generosity, why oppression was more common than freedom, why inequalities of various sorts characterized every social institution. To the founders of the disciplines, the modern distinction between basic and applied scientific concerns would have seemed meaningless, as indeed it was.

The Planning Phase and Editorial Structure

Elsevier's original acquisitions editor for this project, Scott Bentley, discussed the broad outlines of our attack on IESBS 2/e with me in a series of phone calls in the early months of 2010. By May 2010, certain of these outlines had come into sharp relief. There would be a single editor in chief with a tier of 'responsible lieutenants' to assist. These lieutenants started out as advisory editors but soon morphed into the 10 area editors in the final editorial structure. Each area editor would in turn oversee various sections and each section would have its own editor or editors. The original plan was that the area editors would each be responsible for approximately 400 articles and each section editor responsible for about 100 articles, so that no one would have an excessive amount of work compared to everyone else. In the end, however, some sections required more articles and others fewer, so the areas vary from fewer than 300 to more than 600 articles, and the sections vary from fewer than 30 articles to well more than 200.

Prior to my first discussions with Scott Bentley, Elsevier had commissioned about 20 'market surveys,' roughly half from professional librarians and the other half from academics, each focused on 'what was right and what was wrong' with the first edition. The most insistent demand that surfaced was for a fully electronic, computer-searchable work either in addition to or instead of a print version. In the end, both an e-version and a print version are being made available. But there were also consistent concerns expressed about spotty coverage of some areas: no coverage of social work to speak of; inadequate coverage of accounting, marketing, and business; no separate section of criminology; haphazard coverage of applied topics and concerns; and so on. And there were the predictable concerns about undue Western domination of the work.

Working from the 1/e Table of Contents and this stack of 20 surveys, I tinkered for a few months with how best to expand coverage to address the concerns our reviewers had expressed; the result was (more or less) the editorial structure shown elsewhere in the front matter of this work. Thus, the 53 sections of 2/e are basically the 39 sections of the first edition plus sections that were added to cover important emerging areas of research interest (e.g., gay, lesbian, bisexual, and transsexual studies) or to provide deeper coverage of disciplines and subdisciplines that the first edition treated lightly if at all (applied social and behavioral sciences, social work). A

few of the first edition sections were eliminated entirely: specifically, integrative concepts and issues (something of a catch-all category for 1/e articles that were highly interdisciplinary or simply did not fit anywhere else) and gender studies (gender is now so thoroughly integrated into the research and thinking of all the social and behavioral science disciplines and subdisciplines that a separate section was unnecessary and somewhat retrograde). Others were altered or expanded in significant ways (organizational and management studies, for example, became the second edition section on management, organizations, business, marketing and finance; expressive forms evolved into the 2/e section on culture and the arts; linguistics was subdivided into three separate sections; etc.) And some subdisciplinary areas that were part of other sections in the first edition were given their own sections in the second (life course studies; sexuality; criminology; labor studies; and war, peace, violence, and conflict are the most prominent examples), just to ensure adequate coverage.

The Introduction to 1/e (Smelser and Baltes, 2001) discusses at great length the intellectual architecture of the first edition and its evolution; the agonizing decisions about rules for the biographical articles; whether to organize the work by discipline, by concept, by an a priori taxonomy of social science knowledge, or in some other manner; and related structural matters. What resulted in 1/e was something of a hybrid model with some sections clearly representing specific disciplines, others representing 'overarching topics,' still others representing 'intersecting fields,' and so on. My task was far less challenging: I thought the architecture of the first edition served its purposes admirably and so I adopted it wholesale for the second edition, with the small modifications noted above.

While each of the 53 sections of 2/e has some more or less obvious justifying logic or substantive or disciplinary coherence, their arrangement into the 10 areas of the second edition does not. As already indicated, decisions about what sections to include and exclude were made very early in the development of the second edition, based on what was in the first edition, what Elsevier's marketing surveys suggested as significant lacunae, and my own sense of things. The arrangement of the sections into areas came later and was dictated largely by the interests and expertise of those who had been persuaded to sign onto the enterprise. Thus, all the Linguistics sections are in Area Five along with the cognitive and neuroscience sections because Harry Whitaker at Northern Michigan University had been a linguist first, a neuroscientist second, and a historian of psychology third. Likewise, Area Eight contains its seemingly chaotic hodgepodge of evolutionary sciences, genetics, religious studies, science and technology studies, and law because these happen to be the fields of interest of the redoubtable Barbara Prainsack of King's College, London, whose editorial talents are as deep as her interests are broad. Simplifying only slightly, section editors were chosen for their substantive expertise in particular areas of research (as well as their international or cultural 'range'); the plan was that section editors would review each of their articles for completeness of coverage, currency, fairness, and the like. In contrast, area editors were chosen for their breadth of interest and knowledge spanning multiple sections – people who by nature, experience, and training would be good at seeing the big picture. The role of the area editors was to assure that the articles were at least modestly international and interdisciplinary and formed some sort of coherent whole.

As laid out in an early e-mail to one of the area editors, "In my mind, Advisory [Area] Editors are generalists and Section Editors are content specialists. The Section Editors need to bring breadth of knowledge to their responsibilities, of course, but the primary job requirement is expert understanding of the particular field or section. We need section editors who can commission pieces that adequately review past developments in the subject area, but who can also shape their portfolios to identify major unanswered questions and new research developments." This was the general model followed throughout the recruitment process.

The approach just sketched inevitably left a residual area made of up sections that none of the other area editors were willing or able to claim. That proved to be Area Ten. A very large number of scholars from various disciplines and world regions were approached about serving as the Area Ten Editor. All demurred until I approached Martin Bulmer of the University of Surrey, who served the project for about a year but was unable to continue and subsequently left the Board. So for the final year of the project, the editing of Area Ten was done mainly by me.

The online subject classification for IESBS 1/e did not correspond precisely to the sections of the first edition; the subject classifications listed articles by broad general topic regardless of which 1/e section developed them. So for the first year or so, my assistants and I labored to assign every 1/e topic to one of the 53 2/e sections. With 53 sections to populate with articles and about 4000 articles to classify, the process of assigning articles to unique sections occupied huge amounts of time and generated endlessly complicated spreadsheets. (After about a year of this, a document surfaced in the Elsevier archives that showed exactly where each 1/e article had originated.)

Along with populating the 2/e sections with articles, searching for area and section editors occupied a major part of the early going. The original idea was to identify the 10 area editors first and then enlist them in the

search for their section editors, but in fact, these processes were simultaneous and were about half-completed when the two planning meetings were held: the first in San Diego on 19 and 20 May 2011; the second in London on 5–7 June 2011. Although not part of the plan, the first meeting was mostly attended by area editors and the second, by section editors.

The agenda for both meetings was largely identical: achieve clarity on the respective roles of the various editors; solicit advice on filling the unfilled editorial slots; get buy-in on the project *mantra* (internationalism, interdisciplinarity, inclusiveness!); explain the relationship between the first and second editions (e.g., that all 1/e authors would be offered the opportunity to update their articles); explain the process of assigning articles to sections; and the like. In almost all cases, consensus was quickly forthcoming.

The largest substantive change in the second edition is the treatment of psychology. (Whether measured by students, practitioners, professors or programs, psychology is the largest of the social and behavioral sciences.) In the first edition, the whole of psychology was contained within four large sections: clinical and applied psychology; developmental, social, personality, and motivational psychology; cognitive psychology and cognitive science; and behavioral and cognitive neuroscience. Cognitive science and neuroscience are, of course, rapidly growing sectors of the psychological discipline and it seemed appropriate to devote an entire area of the second edition to them. This area contained seven separate sections (three of them devoted to linguistics). And the 'softer' psychological sciences were placed in a separate area comprised of eight sections (including psychiatry and social work). These changes were made to assure that 2/e had adequate coverage of the entire psychological enterprise (a concern that was raised in some of the reviews of 1/e).

The structure of the editorial team was developed to serve two purposes: first, to divide up the labor into manageable parts; and secondly, to assure that every article in the final product would be reviewed by at least three scholars: the respective section editor, area editor, and the editor in chief. Since we were all aware of one another's identities throughout, the review process was not blinded, but every article in this work has been thoroughly peer-reviewed and vetted. In many cases, these articles have been through four, five, six, or even more revisions before being accepted for inclusion in the work.

Recruiting Editors and Authors

IESBS 2/e faced two different recruiting tasks: recruiting editors and recruiting authors. As indicated elsewhere, the original plan was that I would recruit area editors largely from my own personal networks and they in turn would recruit their section editors. In practice, the process was much more convoluted. First off, many of my 'first choice' candidates were hesitant to involve themselves in such a daunting and ambitious project. In some cases, an initial agreement to come aboard was followed a few weeks or months later by withdrawal as the true scope of work came into sharper focus. Some people that I tried to recruit as area editors demurred but agreed to serve as section editors; in other cases, candidates for area editors were nominated by section editors. In a couple of cases, there was a complete team of section editors prior to the successful recruitment of a corresponding area editor. And so on. The process of assembling an editorial team for the project was by no means linear.

Personal networks – mine and those of the people I persuaded to sign on – were the largest single source of ideas for other editors, by far. But personal networks tend to follow disciplinary and national lines and become rather quickly exhausted. In selecting both editors and authors, it was of course essential that all relevant perspectives be covered and that the breadth of fields was adequately represented. So other sources of ideas were tapped: the expertise of the Major Reference Works team at Elsevier; editorial boards of leading journals in the respective fields; Google Scholar citation counts; the knowledge and networks of people who had been involved in preparing the first edition – basically, anywhere names of top scholars in particular areas could be located. I did not keep systematic track of the number of people approached, much less of the outcomes; but in reviewing my e-mail archives from the early period of the project, I probably asked (on average) somewhere between six and eight prospects before I found someone to agree (an average that was highly variable across the areas and sections).

In the initial plan, area editors would recruit their own section editors and the section editors would in turn recruit their own authors, but the reality was again different. Inevitably, my negotiations with prospective editors (both types) would often result in a declination of the editorial role but an offer to write an article on a particular topic (or topics), offers I readily accepted. So in some cases, I had committed authors of particular articles well before I had the corresponding section or area editor in place. And many of the section editors likewise leaned on their area editors and on me for author suggestions, contacts, and outreach. So all the editors

were involved in locating willing authors (and not coincidentally, in making suggestions for articles to be included in the final work).

No one was asked to keep precise statistics on how many authors were sought before an agreeable author was found. My sense is that the 2/e editors had a somewhat tougher time with this than the 1/e editors had (but on the other hand, the 2/e editors had all the 1/e authors to work with, which Smelser and Baltes certainly did not have). The 1/e editors report that about 60% of those invited to write articles agreed to do so on the first 'ask' (with equivalent success rates in each subsequent 'ask'). In 2/e (or so I would guess), the success rate was probably closer to 50% and possibly even lower. They also report that something in excess of 90% of those who agreed to write for 1/e in fact contributed "acceptable entries in time to be included…" In the 2/e case, we found ourselves still soliciting authors within a few weeks of the submission deadline and some dozens of authors pulled out of the project at the last minute. Still, when all the dust settled, there were just about 800 articles planned for both editions that never materialized and both editions ended up with just fewer than 4000 articles. Perhaps these are 'natural limits' for a work of this sort.

Biographies*

In the Introduction to 1/e, Smelser and Baltes provided a short history of and rationale for the decision to include a limited number of biographical articles (150 of them, to be exact). This was evidently a controversial and contested decision since some of those associated with 1/e felt that biographical articles had no place in an encyclopedia focused on substantive knowledge (versus the personalities of those who produced it). As Newton said (paraphrasing a passage from Bernard of Chartres), "If I have seen further, it is by standing on the shoulders of giants" (a passage made famous among social scientists by Robert K. Merton's *On the Shoulders of Giants* (1965)). In other words, discovery is only possible because its discoverer is able to refer to knowledge already gathered and accumulated by his or her predecessors; and since all discoveries – small and large, substantial and minor – contribute to the production and accumulation of knowledge, singling out particular scholars for special attention would be both pointless and invidious.

This position, although understandable, was abandoned in the first edition and remains so in the second, largely because it is not possible to understand the social sciences without knowing the individuals who contributed to it. C. Wright Mills once defined the sociological imagination as the intersection of biography and history (Mills, 1959). To know the social sciences therefore requires biographical and historical knowledge. The social sciences are distinguished from the physical and biological sciences in the way they produce knowledge because individual human beings, including social scientists, invest meaning in their actions. Only through understanding the meaning that individuals give to their actions are social scientists able to provide explanations of human behavior and its outcomes. And what applies to social action in general applies to the production of social science knowledge as well. It thus makes sense to include biographical accounts of social science personages who have been particularly distinguished in making sense of human action and have in turn made major contributions to social science knowledge. To acknowledge individual social scientists with biographical articles is also to acknowledge their special and particular insights.

Once the decision was made to include biographies in 1/e, the next major decision was whom to include and whom to leave out. Two arbitrary but defensible principles governed these decisions: (1) the total number of biographies was not to exceed 150 (chosen because it seemed like a manageable number) and (2) only biographies of the dead would be included. The 1/e section editor for biographies, Karl Ulrich Mayer, consulted handbooks and encyclopedias, asked other section editors to name and rank the most important names in their respective disciplines, ran citation checks, and finally submitted a consolidated list to various experts for review. This resulted in some additions and some deletions and in the end 147 biographies made it into the first edition.

Instructions to authors writing these biographies directed them to include "a brief sketch of the major dates and events in the life of the biographee," to describe "the major contours of the [person's] substantive contribution," and to highlight the "importance and relevance of the biographee's work for the social and behavioral sciences." Largely the same instructions were given to 2/e biographers.

The selection criteria for 2/e were very different. First, on the reasoning that well-done biographies of leading figures is one of the things that draw readers to a work such as this, the total number of biographies was

* My thanks to Andreas Hess for drafting this section of the Introduction.

increased by more than 100 (to just over 250). In a major departure from 1/e, much of the increase is made up of biographies of the living. The 1/e restriction that excluded living persons resulted in anomalies that we thought needed to be addressed. As life expectancy has expanded in the twentieth and twenty-first centuries, so have the life spans of social scientists. Claude Levi-Strauss, to cite one obvious example, lived to the age of 101 years. When 1/e was published, he was in his 90s, was widely cited, was recognized universally as a modern classic, indeed a genius, of social anthropology – and yet, owing simply to his longevity, he was not included in the 1/e biographies. Biographies of, for example, the economist Herbert Simon, the political economist Albert O. Hirschman, the sociologist and philosopher Jürgen Habermas, and the linguist Noam Chomsky were all excluded for the same reason; indeed, Habermas and Chomsky still live as this is being written (Fall, 2014). In all these cases, the major works had been produced decades earlier, their major imprints on the social and behavioral sciences were already evident, their eventual inclusion in works such as this was inevitable. Are readers to be deprived of accounts of their lives, times, and contributions just because they have survived into deep old age?

Once the decision was made to include biographies of the living, however, it was not always easy to decide who among the living merited inclusion. Often the editors had to make decisions on a case-by-case basis, frequently in extended consultation with colleagues or experts in the field. Criteria used to make these decisions were whether the potential biographee had a reputation beyond one culture, nation, or language group; whether there was a record of sustained production over several decades; and whether there was an impact beyond the confines of a single discipline. These criteria reduced our list of suggested biographees considerably. Early lists of candidates numbered as many as 200 new names (in addition to the 147 biographies included in 1/e). In the end, as noted earlier, somewhat more than 100 new names were added.

In a few cases, persons were included that arguably did not satisfy our inclusion criteria. One such is Raul Hilberg, who became famous mainly for having written one very important book, *The Destruction of the European Jews* (1961). Hilberg's book is still regarded as the seminal work in Holocaust studies, a field of research that came to prominence much later; we felt that his signal contributions to Holocaust studies merited a biographical article. Much the same could be said, perhaps, of André Gorz, a well-known social theorist from France, and Albert Memmi, whose work is on colonialism, anticolonialism, and racism. These and other examples could and probably will raise questions about the porousness of our criteria. Whether we were right in giving 'trespassers' their space is open to debate. In any case, whether Hilberg, Gorz, Memmi, and others do or do not merit their biographies is for readers, not us, to decide.

Other important changes in the 2/e biographies section include, first, a conscious effort to attain a better gender balance, including more women both as biographees and as authors; and second, expanding the biographies both geographically and culturally. In the end we made some inroads in both respects but fell short of our internal goals. One of the main reasons for this is that any encyclopedia must, in the first instance, be true to the disciplines it represents. This means being true to the real status of important players, their networks and disciplinary power relations, and their academic capital in their respective fields and beyond. Change in these respects has been noticeable; certainly, the growth of the social sciences in Asia has been remarkable; and in most disciplines, the proportional presence of women has increased. But modest change in the right direction does not a revolution make. Too many nonwhite, non-Western, and nonmale practitioners are still being left out on the disciplinary peripheries and are not fully represented – not in their home disciplines and not in our encyclopedia either.

We state this fact with regret. In many cases, the limiting factor is not excellence but simple visibility. Being part of the trans-Atlantic social science dialogue and engaging this dialog mainly in English translates into more visibility, as discussed earlier. This gets a scholar on the radar screen. Equally excellent work engaging other intellectual dialogues in languages other than English does not. A great many outstanding scholars have thus gone unrecognized in 2/e for precisely this reason. That being said, strenuous efforts were made to make the 2/e biographies more inclusive. Among those included are the Argentinean educationalist Sarmiento, the Brazilian sociologist Cardoso, and the Japanese political scientist Maruyama, to name just a few. This is, however, 'just a few' of the many dozens of prominent social and behavioral scientists 'out there' whom we would have included had we been given more time and more resources (to get non-English works translated, for example). We do feel that we have made some important inroads and beg the reader's understanding of the limits within which we worked. We can only hope that the next edition will strive for more inclusiveness and better representation than we were able to achieve.

Another entirely new feature in the 2/e biographies is the series of 'collective biographies.' In many instances, the intellectual lives of individuals who work in research groups intersect and form a network that makes the

entire group (or paradigm) successful. Examples include articles on the Durkheimians, the Annales School, the Frankfurt School, and several others.

As indicated earlier, instructions to authors were changed little from 1/e. All authors were asked (1) to include the most important biographical facts (country of origin, generation, education, influences, other formative experiences, networks, etc.); (2) to list the most important output (discoveries, publications, etc.) and to briefly discuss the subject matter and content of the most important publications or discoveries; (3) to look at the lasting impact of the person and his or her work (if possible, beyond just one discipline, language group, or culture); and (4) to provide a bibliography of primary and secondary sources related to the biographee and his or her work. Most authors stuck to these guidelines.

Finally, we state for the record that there are a number of important social and behavioral scientists that we would have liked to include but for whom we were unable to find a proper biographer. The search for biographers went on for nearly 4 years. In many cases, our first-choice author agreed at once, but in other cases, we approached four, five, or even more people before an agreeable author was found. And in about two dozen cases, no such author was ever found, with the result that a deserving person's biography had to be dropped. Forgoing a case-by-case discussion of these deletions, let it be simply noted that this is why we have not included biographies of people such as Amartya Sen, the economist and social philosopher; Raymond Boudon, the French sociologist; Ronald Dworkin, the legal theorist; Avishai Margalit, the philosopher; or a collective article for the British Marxist historians (Eric Hobsbawm, E.P. Thompson, Christopher Hill, and Perry Anderson). Perhaps our most regrettable omission is Neil Smelser himself, for whom no biographer could be found despite at least a dozen attempts. (Paul Baltes's biography is included.) Neil is one of the giants on whose shoulders we all stand.

Redundancy

I mentioned earlier that in the beginning of the project, there was no 'map' linking each of the 1/e articles to its respective 1/e Section. Our efforts to create such a map invariably bogged down every time we hit an article that could plausibly belong to any of several sections, which was often. Obviously, it would have been possible to force every article into a 2/e section, but at the time it seemed advisable to involve the editors themselves in these decisions. So on numerous occasions, I distributed lists of 'orphaned' articles (articles for which no home had yet been designated) to the area and section editors, asking for foster parents to volunteer. Eventually, of course, every article found a home, but at a relatively late date in the process, I became aware that a few dozen articles had found more than one home. That is, some of the editors adopted articles without filing the appropriate paperwork with the editor in chief! In such cases, the result was two articles on the 'same' topic. (The 2/e Table of Contents was scoured multiple times looking for precisely these kinds of duplications but in the end, several proved elusive.)

In the large majority of cases, the content of the 'duplicate' articles was sufficiently distinct that both articles were retained, often with some retitling to help readers differentiate between them. For example, readers will find two articles on 'social identity.' One was recruited for the section on social psychology; the other for the sociology section. With rare exception, the two articles discuss different aspects of social identity from entirely different disciplinary angles; indeed, the two articles share only a small handful of common references. So it was an easy decision to retain them both: one appears here as Social Identity in Social Psychology; the other as Social Identity in Sociology. Careful readers will find perhaps a score of similar cases in the encyclopedia.

Alas, in a few regrettable cases, the overlap between duplicate articles was so pronounced that one of the articles had to be deleted. Since by the time these problems surfaced the articles had (often) been written and rewritten several times and had been accepted by both the section and area editors, the last-minute decision to delete a redundant article was painful. My sincere apologies to the authors involved.

Some redundancy in a work of this scope and aspiration is not only inevitable, it is probably also desirable. A reader interested in, say, social inequality will (one hopes) want to know what the sociologists, anthropologists, economists, and geographers all have to say about that topic. And if a few of the many articles on the topic say more or less the same thing, then what harm is done? Editors at all levels were asked to be alert to redundancies across articles and the editorial record shows that many were. That being said, quite a bit of topical redundancy no doubt remains, and that is not (in general) a matter of concern. It is what Smelser and Baltes refer to as the "inevitable residue of overlapping."

The Review Process

Once the table of contents had stabilized, each of the editors was asked to review the 1/e articles assigned to their section or area and come to various decisions. In some cases, 1/e articles could be reprinted more or less 'as is,' with perhaps some updating of references for readers seeking entry points into the current literature. This was especially the case with what were eventually designated as 'legacy articles,' e.g., Gabriel Almond's article on Civic Culture, James Gregor's article on Dictatorship, &c. In other cases, the 1/e articles needed some updating to be suitable for 2/e, either by their original authors when available or by others recruited specifically for the purpose. The general rule was that all 1/e authors would be offered the opportunity to do the updates themselves, and that other authors would be sought in the event of the original authors' declinations. In still other cases, the 1/e article was so obsolete than an entirely new article would be required. And then finally, the review of 1/e articles often revealed areas of current research that were inadequately covered; in these cases too, completely new articles would be sought.

Where appropriate, the relationship between the 1/e and 2/e versions of an article is spelled out in the article tagline. In many cases, there were issues of authorship to resolve — a 1/e article written by *X* and completely revised by *Y* is *Y*'s article although *X* might be identified in the tagline; but what of an article written by *X*, now deceased, and only modestly revised and updated by *Y*? Every decision rule that I formulated to resolve such issues soon confronted an exceptional case where the rule did not seem to apply. So in the end, the only workable rule was that everyone should get proper credit for their intellectual property, whether prime author or reviser, whether living or dead. If exceptions to this rule have crept into the final product (as they almost certainly have), I offer my apologies to those whose work has been slighted or improperly recognized. Deciding on proper authorship for many of our articles was a far more involved and difficult task than expected.

The section editors formed the first line of editorial defense and were the ones to whom article drafts were originally submitted. The section editors read and commented upon the draft articles and returned them to authors for revision. It is a rare article that appears here in its original form: on average, articles were revised two or three times before being sent to the area editors and subsequently on to me; in many cases, it was more like five or six revisions, with subsequent revisions at the request of the area editors and the editor in chief. And in some cases, articles were submitted to outside readers for independent review. As I stated earlier, the reviewing process was not blind, but it was quite thorough, as is reflected in the exceptional quality of the final product.

Internationalism and Inclusivity

A truly *International* Encyclopedia of the Social and Behavioral Sciences would of course require a global network of editors and authors *and* a commitment to internationalize the content of the work wherever possible. With respect to the editorial team for 2/e, this was definitely realized. The section editors and editors in chief who produced the first edition were drawn from only nine countries: The United States, Germany, Italy, Canada, Sweden, Australia, France, Switzerland, and the UK. Two-thirds of those editors were from the USA and only 13% were women. Area and section editors for 2/e represent 21 countries, US scholars make up only 38% of the total, and women comprise 36%. Thus, the proportional representation of women among the editors was nearly tripled in 2/e over 1/e while the predominance of the USA was halved. Nations represented among the editors of 2/e that were not represented in 1/e include Luxembourg, Greece, Finland, Japan, China, Ireland, Singapore, Spain, Russia, Austria, Israel, and the Netherlands. The presence of several Asian nations on this list is particularly gratifying. To be sure, the North Americans and Western Europeans still predominate, but they no longer monopolize the field.

Adding the International Board of Consulting Editors (see the following statement of Acknowledgments) increases the internationalism of the editorial team even further. Of the 45 members of that Board, only 12 (27%) are US social and behavioral scientists. Countries represented on that Board that are not otherwise part of the editorial team include three Central and South American nations (Venezuela, Argentina, Costa Rica), several Asian nations (the Philippines, Malaysia, South Korea, India), a few Western European nations (Norway, Denmark), two representatives from Central and Eastern Europe (Hungary, Croatia), two from the Middle East (Lebanon, Qatar), and one from South Africa. These editions bring to 35 the total number of countries with representation on the IESBS editorial team.

Much the same can be said of the 2/e authors, who are also more international than the 1/e authors had been. Smelser and Baltes noted in their Introduction that while authors from 51 nations were represented in the work,

58% of the authors were from North America and another 35% were from (mainly Western) Europe. "As to gender composition, 21% of the [1/e] authors were women." In 2/e, the proportion of women among the authors has increased slightly to approximately 25% and the percentage of North American authors has declined to fewer than half. Again, North America and Western Europe still contribute the larger share of the 2/e authors but the growing representation of social and behavioral science authors outside the West is both noteworthy and encouraging.

Another important point is that the international scope of the project is much more pronounced than editors' and authors' current affiliations would lead one to conclude. (This would have been equally true in 1/e as well.) Consider, for example, Michiru Nagatsu, author of our article 03053 on the history of behavioral economics. Dr Nagatsu was born in Japan and retains Japanese citizenship but was educated at Exeter and the London School of Economics and Political Science and wrote his IESBS 2/e article while on a postdoctoral fellowship in Finland. Or Guillermina Jasso, area editor for Area Three. Jasso was born in the USA, received her PhD from Johns Hopkins, and is on the faculty at New York University. By any standard, she would count as a US sociologist in our compilations. Yet her parents were Mexican of Basque, Spanish, Portuguese, and Dutch origins; Spanish is her native language; over the course of her distinguished career, she has published with coauthors from Germany, India, Israel, Mexico, the Netherlands, and Sweden; and she holds a permanent research fellowship at IZA, the Institute for the Study of Labor, in Bonn, Germany. Scoring her as 'USA' scarcely does justice to her biography or to the international perspective she brought to the editorial task.

What is true of author Nagatsu and editor Jasso is true in degrees of virtually the entire roster of IESBS participants. If one includes place of birth, citizenship, where educated, sites of research, visiting appointments, sites of fellowships, honorary professorships, invited lectures, and on through the list of highlights in a modern academic career, it is safe to say that every nook and cranny of the globe (save, possibly, Antarctica) is represented somewhere in the biographies of IESBS authors and editors. The true measure of internationalism, in short, is not so much where people come from or where they currently are, but rather the extent to which they bring a sensitivity and commitment to cultural and national differences into their work. Whether this was or was not realized in 2/e is for readers to decide.

Concluding Observations

Smelser and Baltes aspired in the first edition of this work to "assemble the whole range of knowledge – vast and complex as it is – of the social and behavioral sciences in one place." Since what does and does not qualify as 'social and behavioral science' is itself contested, it is not surprising that nearly every one of the market reviews commissioned by Elsevier to guide the development of the current edition noted content omissions in 1/e that reduced its usefulness and that needed to be addressed in a second edition. Critics can and no doubt will say the same about 2/e. I have already mentioned the nearly 800 articles that appeared on the 2/e Table of Contents at one time or another but that will not be found in the final product, either because agreeable authors could not be located or (less often) because agreeable authors never produced an acceptable article. And it is pretty easy to identify whole chunks of present-day social and behavioral science that are given short shrift, or no shrift at all, in this work – not because these chunks were judged to be unimportant but because limits of time, space, resources, and networks meant that some elements of the contemporary social science enterprise never came to our attention.

The social and behavioral sciences begin with what artificial intelligence guru Marvin Minsky once described as a "three pound computer made out of meat" – the human brain, which for all we know is the most complicated three-pound hunk of matter in the universe – and end with a thoroughly globalized culture and social structure that encompasses all aspects of our species' physical, biological, psychological, social, emotional, cultural, and spiritual lives. We are the most successful species ever to have inhabited the planet; we have colonized every inhabitable piece of dirt; our range extends everywhere; all the earth's resources lay at our command. To record all that has come to be known about human origins, evolution, language, culture, and social structure – everything we know about human emotions, identity, love, religion, family, economics, politics, domination, exploitation, and on through a very long list – would require orders of magnitude more volumes than the mere 26 volumes that comprise the present work.

We have come increasingly to the realization that what is social and human about our species is very intimately connected to our biological, genetic, and evolutionary inheritance. At the same time, the brain specifically and biological evolution more generally "cannot be viewed separately from the material, historical and

social circumstances that produce it" (Berntsen and Baker, 2015). As these authors put it, biology and culture are 'mutually constitutive.' Fifteen years ago, the editors of the first edition remarked on "ferment at the boundaries between the biological and the behavioral and social sciences." And while there are still important controversies, much of the ferment has yielded to cooperation as we are just now beginning to explore this endlessly complex web of interconnectedness between our biological and social selves. It is an easy and nearly inevitable conclusion, thus, that the third edition of the IESBS will contain a great deal more of the work being done at this intersection than 2/e was able to accommodate.

To conclude on a purely personal note, the 5 years I have spent working on this project produced many professional and personal gratifications, none quite so delicious as the certain knowledge that I would learn something new every single day. My work on 2/e exposed me to literature I never knew existed and to aspects of the social and behavioral sciences of which I was at best dimly aware. I can only hope that readers who come to these pages will find them as enriching as I have.

ACKNOWLEDGMENTS

A work of this scale is inevitably a communal enterprise involving many hundreds of editors, authors, reviewers, technical support people, colleagues, professional acquaintances, and friends who have provided input, advice, encouragement, and assistance over the past five years. Any listing is bound to be incomplete, so my apologies in advance to those who expected to be mentioned here but are not. Be assured that the slight is not intentional.

My negotiations with Elsevier about this project began early in 2010. By May of that year, I had committed to the project and have been working on it at varying levels of intensity ever since — often on weekends, during holidays, and whenever else I could snatch a useable chunk of time. So my first acknowledgment must be to my wife Chris for suffering through my five year obsession, always with understanding and affection, usually with good cheer. Chris is probably the only person in the world who is happier than I am that the project is now completed.

I must also acknowledge an enormous intellectual debt to the editors in chief of the first edition of the *International Encyclopedia of the Social and Behavioral Sciences*, Drs Neil Smelser and Paul Baltes (the latter now deceased). Dr Smelser was gracious enough to serve as Chair Emeritus of the project's International Board of Consulting Editors and to put himself at my disposal as, in his words, "a battle-scarred veteran." The basic intellectual structure of this work is adopted more or less wholesale from the Smelser—Baltes edition, with a few exceptions noted earlier in the *Introduction*. Without the original to serve as the starting point and blueprint, it is hard to imagine even embarking on such a task, much less bringing it to completion. Their edition was hailed as "the largest corpus of knowledge about the social and behavioral sciences in existence," which is to say that it formed an *extremely* solid foundation from which to build the work you now hold in your hands.

The first edition was organized into 39 sections overseen by a team of 53 section editors. The structure of the second edition is slightly different. It is divided up into 10 broad 'Areas,' each with an Area Editor overseeing the work of between four and eight Section Editors. In all, the second edition is thus comprised of the 10 Areas subdivided into 53 Sections; the 53 Sections were developed by a team of 76 Section Editors. So whereas Smelser and Baltes had 53 colleagues to help complete the work, I had 84 (two of the Area Editors also edited their own sections). On pages i-v in the front matter to this work one finds an Editorial Board list showing the Area Editors, Section Editors, Sections, names, and affiliations of the entire editorial team — a team whose dedication and effort in behalf of the project has vastly exceeded the rate of pay. A more helpful, productive, or delightful group of scholarly collaborators is difficult to imagine.

What readers see in the listed Editorial Structure of the work is the *final* editorial team as it existed when the work went into production. As would be expected in a project of this duration, there was considerable turnover within the team as the project developed and as death, competing demands, and general indifference all took their toll. I am grateful, nonetheless, to everyone who agreed, at least initially, to participate in the project, whether or not they were able to stay involved to the very end.

Susan Hanson (Geography) and Ulf Hannerz (Anthropology) are owed a special note of thanks because, of the 53 Section Editors involved in the first edition, these are the only two who agreed to reprise their roles in the second. (Both also wisely requested and received coeditors to carry part of the load.) Persuading people to serve who had no real idea what they were getting into was challenge enough, but these two suffered through 1/e and were willing to do it all over again for 2/e. And for that, I am especially grateful.

Many of the editors benefitted from the assistance of colleagues and graduate students at their various institutions. There was no mechanism built into the editorial process to keep systematic track of this

assistance and so the listing below is certain to be incomplete. But I can at least acknowledge those of whom I am aware who contributed time and intellectual energy to the effort: Liam Morton and Andrea Livingstone (Psychiatry); Jennifer O'Connor and Alana Dorris (Applied, Industrial and Organizational Psychology); Jen Hanis-Martin (Sexuality); David Budde, Annette Stimmer, Nikolas Ott, and Franziska Pfeifer (Institutions and Infrastructure of Social and Behavioral Sciences); Matthew LeDuc and Scott Freeman (Contemporary Cultural Concerns); and Simone Dudziak (Public Policy). To those named, my thanks. To those omitted, my apologies.

A special note of thanks to Dr Donald J. Barrett. Don was originally recruited to develop an entirely new section of the second edition on Gay, Lesbian, Bisexual, and Transsexual Studies, completed the section in short order, then e-mailed me to ask if there was anything further he could do to be helpful. Consequently, he took a major hand in developing the section on Biographies and was quite helpful with many other sections too. He appears in the Editorial Structure both as a Section Editor and as a Senior Editorial Associate to acknowledge his yeoman service to the entire enterprise. Also listed as a Senior Editorial Associate is my colleague Dr Amy M. Donley, who has been with the project since the very beginning and who, more than once, was all that stood between me and madness. I am proud to count them both as colleagues, collaborators, and friends.

I am also pleased to acknowledge Don Barrett, Andreas Hess, Harry Whitaker, John Berry, Barbara Miller, Scott Bentley, and Claire Byrne for their incisive and helpful commentary on previous drafts of the Acknowledgments and Editor's Introduction.

The project's International Board of Consulting Editors, chaired by Smelser and Dr Peter Marsden of Harvard University, was formed late in 2011 as a 'sounding board' to be used by the Area and Section Editors in searching for topics and authors and to help push for greater internationalism in our coverage. As it turned out, several members of this Board also stepped up to write entries in their areas of expertise. The composition of this Board and the affiliations of the consulting editors (as they were when the Board was first formed, not necessarily as they are today) are as follows: Neil J. Smelser, *University of California, USA*; Peter V. Marsden, *Harvard University, USA*; Ronald F. Abler, *International Geographical Union, USA*; John Bacon-Shone, *University of Hong Kong, China*; Roberto Briceño-León, *Universidad Central de Venezuela, Venezuela*; Roel Bosker, *Rijksuniversiteit Groningen, The Netherlands*; Michael Burawoy, *University of California, Berkeley, USA*; Nestor T. Castro, *University of the Philippines, Philippines*; Dalton Conley, *New York University, USA*; Freek Cronjé, *North West University, South Africa*; Scott Davies, *McMaster University, Canada*; Abdul Rahman Haji Embong, *Malaysian Social Science Association, Malaysia*; Joan-Maria Esteban, *Barcelona Graduate School of Economics, Spain*; Robert S. Feldman, *University of Massachusetts, USA*; Sari Hanafi, *American University of Beirut, Lebanon*; Gudmund Hernes, *Norwegian Business School, Norway*; Sheila Jasanoff, *Harvard University, USA*; Tim Jensen, *University of Southern Denmark, Denmark*; Colin Jones, *University of London, UK*; Nadezhda Lebedeva, *Higher School of Economics; and National Research University, Russia*; Miklós Lévay, *Eötvös Lorand University, Hungary*; Dinka Marinovic Jerolimov, *Institute for Social Research, Croatia*; Laurie M. Joyner, *Rollins College, USA*; Ferenc Kiefer, *Hungarian Academy of Sciences, Hungary*; Pan Suk Kim, *Yonsei University, South Korea*; Katsuya Kodama, *International Peace Research Association; and Mie University, Japan*; Allan Lavell, *Facultad Latinoamericana de Ciencias Sociales (FLACSO), Costa Rica*; Jake Lynch, *University of Sydney, Australia*; Cecilia Mabragana, *Consejo Nacional de Investigaciones Cientificas y Tecnicas (CONICET), Argentina*; William McBride, *Purdue University, USA*; Ishwar Modi, *University of Rajasthan, India*; Leonardo Morlino, *School of Government, Italy*; Melvin L. Oliver, *University of California, USA*; Angela M. O'Rand, *Duke University, USA*; Kenneth Prewitt, *Columbia University, USA*; Thilo Rehren, *University College London Qatar, Qatar*; Colette Sabatier, *Université Victor Segalen, France*; Philip Schofield, *University College, UK*; Rainer K. Silbereisen, *University of Jena, Germany*; Chamhuri bin Siwar, *National University of Malaysia, Malaysia*; Tom W. Smith, *World Association for Public Opinion Research, USA*; Catalina Smulovitz, *Universidad Torcuato Di Tella Miñones, Argentina*; Philip Spinhoven, *Leiden University, The Netherlands*; Sukhadeo Thorat, *Indian Council of Social Science Research, India*; Nigel Thrift, *University of Warwick, UK*; John R. Townshend, *University of Maryland, USA*; Gisèle Yasmeen, *Social Sciences and Humanities Research Council of Canada, Canada*.

Searching for an editorial team to represent every social science discipline and every region of the globe quickly exposed the deficiencies in my personal network, so I am indebted to a very large number of scholars around the world for calling names of prospects to my attention, allowing me to drop their names in the recruitment effort, or otherwise helping me find people with the expertise and commitment required for the job. In most cases, this is a list of people who were invited onto the editorial team in some capacity,

demurred, but made valuable suggestions about others to contact. In several cases, people are listed because they engaged me in intellectual discussions about the structure, format, and even advisability of this work, or simply replied to a cold-call e-mail in pleasant, kind, helpful, or informative ways. Again ignoring the risk of omission, my sincere personal thanks to those named below for their contributions large and small to the final product:

Doug Anderton, Juri Allik, George Armelagos, Susan Ayers, Amanda Baumle, Janeen Baxter, Jess ben-Habib, Joao Biehl, David Blanchflower, Hans-Peter Blossfeld, Jason Boardman, Dorret Boomsma, Roel Bosker, Henry Brady, Martin Bulmer, Craig Calhoun, Miguel Centeno, William Cockerham, Mark Nathan Cohen, Amelie Constant, Simon Cottle, Connie Citro, Eileen Crimmons, James Curran, Scott Davies, Donatella Della Porta, George Downs, Francis Dodoo, David Dozois, Sonja Drobnick, Jaap Dronkers, John Dryzek, Riley Dunlap, Lauren Edelman, David Elesh, Paula England, Nancy Eisenberg, Geoffrey Evans, Miriam Faust, Robert Feenstra, Marcus Feldman, Stanley Feldman, Ronald Fischer, James Fowler, Jeremy Freese, Angela D. Friederici, Michael Frumpkin, Masahisa Fujita, Nicole M. Gage, Nancy Gallini, Rosemary Gartner, Morton Ann Gernsbacher, Robert Goodin, John Grattan, Lance Gravlee, David Greenberg, Wendy Griswold, Melanie Guldi, Monica Das Gupta, Peter Hatemi, Robert Haveman, Karen Heimer, John Hibbing, Sarah Blaffer Hrdy, Sheila Jasanoff, Kelly Kadera, Cigdem Kagitcibasi, David Kavanaugh, Roger Keil, Byungkook Kim, Rob Kitchin, Jack Knight, Lyle Konigsberg, Candace Kruttschnitt, Helen Ladd, Phillip Lane, Graeme Lang, Janet Lauritsen, Ashley Leeds, Evelyn Lehrer, Richard Lerner, David Lewis, Tim Liao, Tom Linneman, Norman Long, Karen Lyons, Ruth Mace, Gary Marks, Herbert Marsh, Karl-Ulrich Mayer, Lorraine Mazerolle, Rose McDermott, Susan Michie, Harry Minas, Peter Miller, S. Phillip Morgan, Victor Nee, Vin-Kim Nguyen, Paul Nieuwbeerta, Helga Nowotny, Howard Nusbaum, Claus Offe, Thomas Ollendick, Joan Orme, Dennis O'Rourke, Michael Overington, Catherine Panter-Brick, Susan Parnell, Deborah M. Pearsall, Gerard Pfann, Jon Pierre, Mike Ping, Jennifer Platt, Ken Prewitt, Cathy Price, Jill Quadnagno, Charles Ragin, Thilo Rehren, Ben Rosamond, Bo Rothstein, Beth Rubin, Heinrich Sauer, Peer Scheepers, Ralf Schwarzer, Moshe Semyonov, Michael Shanahan, Sara Shostak, Alan Sica, Rainer K. Silbereisen, Beth Simmons, Catalina Smulovitz, Michael Sobel, Diane Stone, Jill Stephenson, Rafe Stolzenberg, Miron Straf, Richard Swedberg, Alan C. Swedlund, Sidney Tarrow, Jacques-Francoise Thisse, Stefan Timmermans, Florencia Torche, Erik Tsang, Judy Treas, Billie Turner, Cees van der Eijk, Paul van Lange, James Vaupel, Karin Wahl-Jorgensen, Mitchell G. Weiss, Neil Whitehead, Pamela Wilcox, Bjorn Wittrock, Cornelia Woll, Gisele Yasmeen, and Barbie Zelizer.

Gratitude is owed as well to the many colleagues at Elsevier who contributed to the production of this volume. My first debt is to Claire Byrne, the project's Content Project Manager and the head of the Major Reference Works (MRW) team that managed the day-to-day *Sturm und Drang* of the project: aggrieved, confused, or delinquent authors, missed deadlines, testy and intransigent editors, and the often-maddening work style of the Editor in Chief. I am sure there were days when Claire wanted to tear her hair out, but to external appearances, she was an island of calm in a sea of turmoil. She was also exceptionally good at her job.

Claire's MRW team comprised Richard Berryman, Will Bowden-Green, Esmond Collins, Mark Harper, Sam Mahfoudh, Mike Nicholls, Gemma Tomalin, Joanne Williams, and Marise Willis. No matter what issue or problem I faced, one of these fine, capable people was always available to step up with a solution, invariably offered in a spirit of cooperation and good cheer. They have been to IESBS 2/e what tech support is to the modern computerized office. Getting this work completed without their help is inconceivable.

Thanks also to the succession of Elsevier's Acquisitions Editors who managed the finances and internal politics of the project: to Scott Bentley, whose gentle suasions pulled me into the project in the beginning; to Karen Maloney and Peter Labella who ran the show in the middle period; and to Lisa Tickner who was in charge at the very end. These are the people on the front line in the endless war between the publisher, who wants things done now and at minimal expense, and the Editor in Chief, who was always asking for more time and more money. The many dozens of amicable compromises necessary to bring the project to completion were all ably negotiated by Scott, Karen, Peter, and Lisa, and for that, I am grateful indeed.

The University of Central Florida and its Department of Sociology have provided a congenial home for the project. My thanks in particular to Dean Michael Johnson; to the current and former chairs of my department, Jana L. Jasinski and Libby Mustaine; to my faculty colleagues Liz Grauerholz, Phillip 'Hutch' Pollock, Bruce Wilson, Melanie Guldi, Stacy Barber, Tosha Dupras, and John Schultz; and to current and former graduate students Thomas Hall, Sara Strickhouser, Betsy Swart, Jordana Navarro, Marie Gualtieri, Shannon Simone, and Shannon Frey.

And most of all, my sincere thanks to the many thousands of authors whose work this is. When comparing the quality of the work contained within these pages to the authors' honoraria, it is obvious that IESBS 2/e is an act of collective charity by our authors to the disciplines they represent. It is my pleasure to thank our authors on behalf of the global social science community.

GUIDE TO USING THE ENCYCLOPEDIA

Structure of the Encyclopedia

The material in the Encyclopedia is arranged as a series of articles in alphabetical order.

There are four features to help you easily find the topic you are interested in an alphabetical contents list, cross-references to other relevant articles within each article, subject classification index, and a full subject index.

1. Alphabetical Contents List

The alphabetical contents list, which appears at the front of each volume, lists the articles in the order that they appear in that volume of the Encyclopedia. It includes both the volume number and the page number of each article.

2. Cross-references

All of the articles in the Encyclopedia have been cross-referenced. The cross-references, which appear at the end of an article as a See also list, serve three different functions:

a. To draw the reader's attention to related materials in other articles.
b. To indicate material that broadens and extends the scope of the article.
c. To indicate material that covers a topic in more depth.

3. Subject Classification Index

This index appears in Volume 26 and groups articles under subject headings that reflect the broad themes of Social and Behavioral Sciences. This index is useful for making quick connections between articles and locating the relevant article for a topic that is covered in more than one article. Under some section headings, you will find subheadings, if it is appropriate for the articles in a subject area to be grouped into more specific subareas.

4. Contributors

At the start of each volume, there is list of the authors who contributed to that volume.

5. Index

The index appears in Volume 26. The index includes page numbers for quick reference to the information you are looking for. The index articles differentiate between references to whole article, a part of an article, and a table or figure.

Taboo

Michael Lambek, University of Toronto, Toronto, ON, Canada

This article is reproduced from the previous edition, volume 23, pp. 15429–15431, © 2001, Elsevier Ltd.

Abstract

A concept assumed in the Victorian period to be central to the religions of supposedly less evolved societies, the term today is generally used to refer to proscriptions grounded in custom or religion rather than in bureaucratic law or common sense. Derived originally from Polynesia, the subsequent career of the concept has been paradigmatic of anthropological theory more generally. In the latter half of the nineteenth century taboo came to epitomize the essence of primitive thought. The reification of taboo was debunked soundly in the mid-twentieth century by Steiner. Freud and Lévi-Strauss each emphasized the structural significance of a universal incest taboo, while Douglas demonstrated the role of taboos in maintaining systems of classification and moral order. Others have examined taboos from the perspective of those who maintain them, drawing on phenomenology or practice theory to show the relevance of taboos as acts for understanding the constitution of the socially located moral person or, conversely, have explored the efflorescence of taboo violations or fantasies at sites and moments of moral vertigo, social dislocation, and state impunity or simply recognized the centrality to human experience of power and danger generated through negation, transgression, and excess.

A concept assumed in the Victorian period to be central to the religions of supposedly less evolved societies, the term taboo today generally is used to refer to prohibitions grounded in custom or religion rather than in bureaucratic law or common sense and hence bearing some moral weight. Taboos can be widespread, observed over the long term, internalized, and deeply felt, as in the case of incest taboos, or applied temporarily with respect to specific persons, acts, conditions, and objects. This article reviews the history of the concept which can be seen to reflect the development of anthropological theory more generally.

Taboos, Social Order, and Moral Persons

The word taboo is originally Polynesian. Via the writings of explorers like Cook and missionaries like Ellis it rapidly entered ordinary usage in Victorian England. In 1842 the 7th edition of the *Encyclopaedia Britannica* defined taboo succinctly as, 'A word used by the South Sea islanders, and nearly of the same import as prohibited or interdicted. It applies equally to persons and things, and is also expressive of anything sacred, devoted, or eminent' (quoted in Steiner, 1999: p. 164). In the hands of Robertson Smith and Frazer, taboo came to epitomize the essence of primitive thought, distinguishing it from civilized religion (i.e., the Judaeo–Christian tradition) in the way it combined holiness with defilement. In a deconstructive work equivalent to that which Lévi-Strauss performed for totemism, Steiner admirably summarized and critiqued the use of the term through the first half of the twentieth century, demonstrating the problems with applying a culturally particular concept in a comparative and evolutionary fashion. Steiner showed that it was impossible to separate defilement from the sacred in any consistent manner. Steiner's critique of the abstraction and reification of taboo has been pursued by MacIntyre, while his insights into its significance in Polynesia have been considerably enlarged by Gell, Sahlins, and Valeri.

The most profound reflections on taboo have concerned its universal social basis. Both Freud and Lévi-Strauss have seen the incest taboo as fundamental to the constitution of society. For Freud, internalizing prohibitions against intra-familial violence and sexual relations establishes the conditions for the emergence of kinship and moral conscience. Lévi-Strauss argued that the incest taboo generates inter-familial relations, providing the basis for the exchange of women (or marriage partners of either sex) that in effect constitutes society. Whereas Freud in *Totem and Taboo* emphasized the temporal significance of the incest taboo (whose phylogenetic origin in actual historical events is largely dismissed by anthropologists) and the implications for intrapsychic and intrafamilial relations (which finds broader though not unanimous support), Lévi-Strauss argued that the incest taboo forms the logical basis of society and is rooted in the universal mental capacity to make categorical binary distinctions, notably those between self and other, culture and nature. In an ambitious attempt to unify and critique the theory, Rubin added the injunction against homosexual relations.

It is Lévi-Strauss's emphasis on classification that has most influenced subsequent analyses of taboos and has proved fruitful in understanding their varied and often ostensibly trivial content. Drawing on their common heritage of Durkheim, both Douglas and Leach emphasized the role of taboos in protecting systems of social classification by banning anomalous or marginal words, objects, and practices that

might violate the order of the categories or blur their distinctions. The title of Douglas's major work, *Purity and Danger* (1966), captures the crux of her argument perfectly. Dirt, or that which is viewed with revulsion and hence tabooed, is 'matter out of place' and hence always relative to a system of classification but also dangerous for it. Building on Steiner, Douglas argued convincingly that individual taboos can only be understood as parts of larger social wholes; that taboos are not false or failed attempts at science; that Western lives are replete with taboos which are no more or less rational than those of other societies; and that without principles of restriction, conceptual and moral discrimination would be compromised and the ensuing freedom of both thought and action would be hopelessly chaotic.

Douglas's argument has inspired much subsequent work, especially on gender, the body, and food. Among the merits of her approach is the ability to show structural similarities in taboos, whatever their specific content, both within a given society, between societies, and across both ostensibly secular (e.g., hygiene, courtesy) and sacred realms. Somewhat more controversial have been attempts both to illustrate how taboos in various orders of phenomena (notably diet) reflect concerns with the maintenance of social boundaries and divisions and, at a greater level of abstraction, to plot the degree of general interest in maintaining the purity of classificatory orders against the underlying nature of the social relations (the type of society, relatively defined). Following one strain of Durkheim's thought, Douglas gives primacy to the form and integration of social groupings and thus, despite her radical demonstration of the contingent nature of particular taboos, the argument appears rather conservative. Purity and impurity are not only relative to a system of categories, but this system may also be arranged with respect to a hierarchy of sanctity within a holistic universe, as epitomized by Dumont's account of the South Asian caste system. Ensuing questions about the relationship of sanctity and encompassment to power have been much debated.

While the presence of taboos is universal, their substance and direction are not, giving rise to culturally specific social orders. In some parts of the world, like eastern Indonesia, prescriptive rules are emphasized, while in others, like Madagascar, proscriptions are pervasive (Lambek, 1992). Lévi-Strauss demonstrated that specific positive rules of marriage – made possible by the underlying incest taboo – generate certain patterns of relationship over time. Taboos, by contrast, in that they do not specify what must or should be done, allow greater degrees of freedom. Yet, as Fortes argued, they are also grasped more easily and internalized more deeply than positive injunctions.

While taboos usually are analyzed as discursive elements, it is important to understand that they become realized in practice. Often the most consequential taboos are the least explicit. If in a structural model the semantic contents of taboos distinguish who or what one is not, from a practice perspective it is the observance of the taboo that substantiates who one is. Van Gennep saw taboos as acts of obligation, creating both continuity and separation. Fortes emphasized the morally binding quality of taboos and the personal significance of observing them for the internalization of an enduring identity and the acknowledgment of dependence on, and obligation to, higher authorities or values. Moreover, taboos 'crystallize these abstract norms in concrete objects and precise rules of conduct which are the more effective because they are of no utilitarian or rational value' (Fortes, 1987: p. 129).

Fortes observed both the essentially inward orientation of taboos, especially with respect to eating, and their continuous nature. An important consequence of the fact that taboos are phrased in the negative is that their observance is a relatively continuous and private form of action, whereas carrying out a positive order is a discontinuous and relatively discrete and public act. Hence while the power entailed in observing a taboo may be less explicit and forthright than a direct command, the implications may be more profound.

Defiance of taboo may challenge subjection, identity, and value at quite a deep level.

Taboos, then, are not merely imposed, lifted, or carried out in discrete acts but observed continuously. As practical disposition the observance of taboos exemplifies Mauss's and Bourdieu's notion of the habitus and Aristotelian virtue that underlies it. Although not always accepted happily, taboos index personal dignity and (self-)respect, and insofar as they are embodied statements, they may be understood as acts which performatively establish and maintain moral states of social commitment and individual conscience. Moreover, in the visceral reactions to the violation of taboos (nausea, disgust, etc.), underlying social conventions are naturalized. Hence, as Douglas also intuits, taboos do not merely signify social or cosmological order but, in acts of separation, commitment, and principled refusal, they constitute it.

Taboos may be understood phenomenologically with respect to a dialectic of subject and object. Gell argues that it is through taboos, applied at varying levels of specificity across social categories, and operating as intentional, if negative, engagement with the world, that the ego or self is constituted. 'To observe a taboo is to establish an identifiable self by establishing a relationship (negative in this case – *not* eating) with an external reality such that the "self" only comes into existence in and through this relationship' (1979: p. 136). 'Taboos on eating, on killing, on sexual intercourse, on looking at, touching, etc., together circumscribe a "hole" in the texture of shareable intersubjective reality which, privileged with respect to a specific individual, constitutes his soul, or ego, or personality. Taboo does more than express the self: it constitutes the self" (1979: p. 137). When Gell's argument that taboos carve out the self is combined with Lévi-Strauss' argument that taboos generate exchange and hence society, it is clear that the self is relationally constituted, simultaneously held apart from and connected to others, simultaneously social and itself. There is a dynamic quality here: Umeda of Papua New Guinea alternate phases of taboo and consumption; in Gell's analysis the taboo phase restores the integrity of the ego by 'reconstituting it as a closed system' (1979: p. 146). Elsewhere Gell (1995) generalizes the logic of taboo in its original Polynesian locus where it produced differentiation in a cosmos in which sacredness was immanent rather than transcendental.

Transgression

One of Freud's central arguments concerned the essential ambivalence of taboos, understood as the coalescence of the conflict between a desire and its refusal, attraction, and

repression. It is clear that anticipation or suspicion of the violation of taboos often produces visceral reactions – whether laughter, lust, or queasiness – disgust rather than mere indignation. Moreover, because the embodied practice of powerful taboos goes without saying, their pervasive presence is only highlighted by the observance of violation. That is to say, taboos are often indicated through instances of their transgression, in effect, a double negation. As Douglas, Gluckman, and Turner showed, suitably framed transgressions may provide central episodes in religious experience, moral education, and social transition, but otherwise they are perceived as highly threatening. Transgressions may establish political dissent or domination, but they are also the source and substance of neurotic illness, social panic, and much fantasy.

Stallybrass and White (1986) conjoined these ideas with Bakhtin's notion of the carnivalesque and Elias's history of manners to explore the significance of taboos in the historical constitution of the European middle class. The rigorous expulsion of what was perceived as disorderly, low, and carnal has produced, in their view, various 'returns of the repressed.' These include nostalgia, longing, fascination, and even the academic preoccupation with the body.

While some people continue to argue for a biological basis to the incest taboo (and possibly certain other widespread prohibitions), the increased acknowledgment of the prevalence of actual incestuous relations supports those theories that find the source of taboos in culture or society and human ambivalence. Indeed, the question has been raised whether incest taboos are any longer necessary and whether they have been *de facto* lifted, or at least limited. On another front, the violence and rape characteristic of twentieth-century warfare, and the torture carried out by repressive political regimes, must be recognized. Indeed, these might be viewed as deliberate and state-sanctioned liftings of taboos in order to maximize personal violation. However, due in part to fears of contamination that accompany any discussion of transgression, research has focussed more on the condition of victims than the acts of perpetration.

Of course, the presence of taboos has always generated fantasies of transgression. These are often difficult to distinguish from actual transgressions and at the same time may produce transgressive acts of their own, as in the 'de-repression' characteristic of accusations of witchcraft and child abuse prevalent in recent years in North America and northern Europe but also globally (Comaroff, 1997; LaFontaine, 1998). The need for moral discernment is not always matched by epistemological clarity, yet the fantasies and acts, characteristic of sites and moments of moral vertigo and vacuum, underline the near universality of disgust in the face of certain kinds of physical and sexual brutality and invasiveness, the universal need for avenues for the exercise of dignified moral agency, and the place of taboos among such means.

Conversely, it could be argued that the preceding discussion suffers from an overly socialized, moralistic, and tame conception of taboos; that negation and excess are central to religious experience; and that transgression be recognized as 'the ultimate sacred act' (Taussig, 1998: p. 361).

Abstract

In his initial article in the *International Encyclopedia of Social and Behavioral Sciences* titled "Tacit Knowledge: Psychology of," Reber explored the ideas presented in Michael Polanyi's original work on tacit knowledge and discussed some of the trends, controversies, and disputes surrounding the topic. We build on this to show that as tacit knowledge has been diffused into management research, similar challenges, debates, and controversies about tacit knowledge continue.

Tacit knowledge is gaining increasing importance in a number of research domains because of its relation to value creation and a variety of organizational and individual processes, coupled with the challenges of leveraging and scaling the benefits of know-how that is embedded and difficult to articulate (Coff et al., 2006). In his initial article in the *International Encyclopedia of Social and Behavioral Sciences* titled "Tacit Knowledge: Psychology of," and in his previous work (1992, 1993), Reber explored the ideas presented in Michael Polanyi's (1958, 1966) original work that viewed tacit knowledge as information that was intensely personal, introspectively opaque, and communicatively unresponsive. Complex knowledge that is abstract in nature and deeply causal – typically referred to as tacit – has been a disputed and controversial domain for decades. Polanyi wrote that we know more about familiar conceptual domains than we can articulate and described how his own early life as a creative scientist was largely a struggle to make tacit knowledge more explicit and open to communication and articulation. The goal of converting tacit understanding to explicit and more easily shared knowledge dominated the attention of those conducting research in this arena.

Reber focused his article in the first volume of this encyclopedia on the psychology of tacit knowledge, which he acknowledged was often described in the psychology literature using a variety of other terms (e.g., implicit, procedural, covert, nonconscious). These terms describe knowledge that is acquired and used with little in the way of top–down control of consciousness. His article focused on four classical topics that have dominated psychological thought since the 1970s: perception, memory, learning, and motivation. He also outlined the methodological, functional, and representational disputes and controversies that have plagued and continue to plague literature on tacit knowledge.

The purpose of this article is not to update Reber's work and discuss the recent psychology-based arguments and directions of tacit knowledge research, but to show that as tacit knowledge has been applied to other domains and specifically as it has diffused into management research, similar challenges, debates, and controversies about tacit knowledge continue.

Why Is Tacit Knowledge So Important to Management Research?

During the last few decades, tacit knowledge has undergone a resurgence of attention in many disciplines and domains. Management research is one of the domains where knowledge and specifically tacit knowledge has become an important concept to grasp and to learn how to actively manage. Over the past two decades, the interest in and importance of understanding tacit knowledge has grown and proliferated into a variety of management research field areas such as organizational knowledge, the knowledge-based view, knowledge-creating organizations, the resource-based view of the firm, and strategic human resource management (Grant, 1996; Nonaka and Takeuchi, 1995; Orlikowski, 2002; Tsoukas, 1996). This attention has elevated the knowledge-based view of organizations to one of the main theories in management research that attempts to explain firm performance and more importantly to explain why some firms are able to outperform others and to sustain a competitive advantage (Eisenhardt and Santos, 2002). The foundation of the knowledge-based view is that one of an organization's main functions and what an organizational system can efficiently do is generate, combine, recombine, and exploit knowledge which leads to performance (Kogut and Zander, 1996). This has led many management researchers to identify knowledge as the most strategically significant resource of the firm (Dierickx and Cool, 1989; Grant, 1996; Kogut and Zander, 1992). However, researchers acknowledge that simply having strategically valuable knowledge within an organization is a necessary, but not sufficient, condition for superior performance. Knowledge must be effectively used, leveraged, and scaled within an organization and at the same time protected from imitation by rival firms to realize and sustain performance benefits.

Therefore, underlying most recent research is the need to uncover and understand characteristics of knowledge that relate to the generation, combination, recombination, and application or use of knowledge and/or knowledge workers. At the foundation of knowledge management theories, however, two fundamental questions identified by Grant

(1996: 110) remain unresolved: (1) What is knowledge? (2) What are the characteristics of knowledge which have critical implications for management? Answers to these two questions remain elusive and controversial. Within the knowledge-based view of organizations, finding answers to these two questions may provide direction, not only for future research, but for the creation of sustainable competitive advantages in organizations.

Two Schools of Thought on the Meaning of Tacit

The disputes and controversies surrounding organizational knowledge can be linked to the development of two distinct views of organizational knowledge. On the one hand, the 'commodity' school has focused on understanding the different types of 'knowledge' in an organization and then linking these types to other organizational phenomena such as innovation, alliance formation, and performance (e.g., Becerra et al., 2008; Nonaka and Takeuchi, 1995). On the other hand, the 'community' school has focused on 'knowing.' This second school has emphasized the lively act of knowing something and using that knowledge to achieve desirable outcomes (Brown and Duguid, 1991; Cook and Brown, 1999; Orlikowski, 2002; Pfeffer and Sutton, 1999; Tsoukas, 2003). Although potentially relevant to one another, the two schools of thought evolved almost independently with little theoretical integration. Among knowledge management theorists, however, a debate remains about what the important and meaningful characteristics of knowledge are and how they should be studied (Newell et al., 2002).

Commodity View

Advocates of the commodity or possession perspective stress two distinct kinds of knowledge: tacit and explicit. This distinction was followed with many other terms such as local versus universal, codified versus noncodified, procedural versus declarative, and know-how versus know-what to describe the different characteristics of distinct types of organizational knowledge (Orlikowski, 2002). Perhaps the most significant piece of work from the commodity perspective of organizational knowledge is the influential book *The Knowledge-Creating Company* by Nonaka and Takeuchi (1995). They suggested knowledge creation and management is an iterative process in which tacit knowledge and explicit knowledge are converted interchangeably in a continuous cycle through the four modes of socialization, externalization, combination, and internalization. Socialization involves the implicit sharing of tacit knowledge, externalization involves the transformation of tacit to explicit, combination involves conveying explicit knowledge from one person to another to make it a collective 'stock' of knowledge, and internalization involves the conversion of explicit knowledge back to its tacit form.

Knowledge management theorists apply the distinctions of tacit versus explicit, and similar taxonomies such as procedural versus declarative to focus on knowledge as a commodity that can be documented, stored, repackaged, and distributed. Research from this perspective has resulted in many important and useful theoretical contributions on how crucial organizational knowledge can be codified and transmitted in a formal, systematic way to influence or trigger certain organizational outcomes. Knowledge has commodity-like characteristics and can be accumulated, transferred, and stored independently of an individual (Buckley and Carter, 1999). In other words, knowledge is regarded as "an objective entity … as a thing out there that can be transmitted or exchanged without any intervention by a cognizing mind" (Ringberg and Reihlen, 2008: 914). An important emphasis from this perspective is developing processes and organizational mechanisms that enable the transformation of tacit understanding into explicit knowledge by encouraging individuals to put forth the required degree of effort.

The Community Perspective

The community view of knowledge management research is somewhat critical of a purely commodity or possession perspective. Scholars have argued that knowledge is not an 'object' that can be stockpiled or stored, but more of active phenomenon that cannot be separated from the very act of knowing something (Brown and Duguid, 1991, 2001; Cook and Brown, 1999; Orlikowski, 2002; Pfeffer and Sutton, 1999; Tsoukas, 2003). Central to the community view is Lave and Wenger's (1991) communities-of-practice learning theory which attempts to shift the focus to exploring the links between knowledge and the actions of organizations and the individuals within them. To communities-of-practice researchers, the notion that knowledge can be explicit and quantifiable draws a problematic distinction between knowledge as a tangible good and the use of that good in practice (Pfeffer and Sutton, 1999). Community-of-practice research argues that it is often impossible, or at least unproductive, to attempt to separate knowledge from how individuals act on what they know.

The difference between the two research streams is made clear by understanding the distinction between *knowledge* implying something that can be located and is independent of both the individual who has the knowledge and the context in which understanding takes place, and *knowing* which implies a process or action of knowers (Pfeffer and Sutton, 1999). A community-of-practice outlook explores the actions that people undertake while solving problems during their day-to-day interactions in the real world (Brown and Duguid, 2001; Cook and Brown, 1999; Orlikowski, 2002). In this research stream, organizational knowledge is seen through the lens of its manifestations in the activities that make tacit knowledge a part of every organizational action (Nag et al., 2007). Specifically, distinctions between explicit and tacit knowledge are not sufficient to understand all somebody knows; it is also necessary to understand the concept of knowing through action or experience-based know-how (Cook and Brown, 1999). Brown and Duguid (2001), and others (Blackler, 1993; Spender, 1996; Tsoukas, 1996) argue that a knowing perspective more accurately reflects Polanyi's conclusion that all knowledge has an inarticulate component (Brown and Duguid, 1991; Cook and Brown, 1999; Nag et al., 2007; Orlikowski, 2002). Community researchers argue that Polanyi did not write about two different types of knowledge

or describe two ends of a continuum. Instead, they emphasize Polanyi's proclamation that tacit knowledge is a vital component of all knowledge; in other words, all knowledge is tacit or at a minimum incorporates some elements of tacit knowledge (Botez, 1998). From this perspective, what matters most is the proportion of embedded or experience-based know-how reflected in what is known.

Knowledge-in-Practice

More recently within the knowledge management literature researchers have attempted to integrate the two disparate views of knowledge while trying to understand the critical characteristics of knowledge from a knowledge-in-practice (KIP) perspective (McIver and Lengnick-Hall, 2011; McIver et al., 2012, 2013, 2010). Building on the community-of-practice literature, McIver and colleagues focused on the practice aspects of understanding and using knowledge. A practice is an activity which is sustained and reproduced over time and is critical to the analysis of knowledge (Duguid, 2005; Lave and Wenger, 1991). According to Cook and Brown (1999), *practice* implies doing and refers to activities of organizational members informed by meanings. In other words, in knowledge management research practice refers to *the way in which work gets done and knowing how to do it* (Brown and Duguid, 2001: 200).

McIver et al. (2010, 2012, 2013) define KIP as the information and know-how involved in the sequences, routines, capabilities, or activity systems in an organization. They define information as the facts and data that can be understood, stored, and transferred. Information reflects the commodity perspective of knowledge. Know-how is defined as the skills and expertise that are action-based and reflect the 'knowing' view of knowledge. However, since KIP requires both information and know-how, it invariably incorporates the important tacit dimension or tacit knowledge. A KIP perspective underscores how all knowledge, or KIP, has a tacit component. While the conventional wisdom within the management literature has typically been that tacit knowledge is synonymous with difficult to learn, difficult to transfer, and hard to understand, the accuracy of this assumption is now being questioned. It seems that focusing solely on distinctions between tacit and explicit knowledge can lead to misrepresentation of the phenomenon.

Drawing from communities-of-practice research (McIver et al., 2013) added the dimension of learnability to help clarify the understanding of knowledge in organizations. They defined the tacitness of knowledge as *the degree to which the know-how involved in an organizational practice is unobservable, difficult to teach, unspecifiable, and/or highly embedded in the setting* (McIver et al., 2013). This definition distinguishes difficult to learn from difficult to teach, and separates the concept of hard to understand from challenging to articulate or specify and explicitly recognizes the embedded or situated nature of tacit knowledge. In addition, by defining tacitness as a characteristic of knowledge that varies in degree, this definition incorporates Polanyi's actual premise that all knowledge contains some measure of tacit understanding. This definition suggests that what varies is the proportion and role of tacit knowledge within different activities or practices within organizations. This view contrasts with perspectives that specify tacit and explicit knowledge as either two separate and independent dimensions or as opposite ends of a continuum and argue that tacit can be converted to explicit knowledge. The McIver et al. (2013) definition shows that all practices have a tacit component.

McIver et al. (2013) explain that there is a second essential dimension of KIP that is generally neglected: learnability. They define learnability as *the type and amount of effort, study, accumulated comprehension, and expertise that is involved in understanding the information and know-how for accomplishing work practices*. Learnability captures the ease (or difficulty) which new or occasional workers experience trying to perform certain work practices. Learnability distinguishes between KIP that is difficult to learn and KIP that is relatively easy to learn regardless of the degree of tacitness. Incorporating learnability into an understanding of tacit knowledge highlights two overlooked conditions – KIP with a high degree of tacitness that is easy to learn and KIP with a low level of tacitness that is quite difficult to learn. This distinction addresses the implicit, but arguably inaccurate, assumption noted previously that all tacit knowledge is difficult to learn. If all knowledge when used in the act of knowing has a tacit component, there must be a way to distinguish between knowledge or activities as practices that are difficult to grasp and knowledge in organizations that is not as difficult to master. Introducing the concept of learnability underscores important distinctions between learning and teaching, codification or observation and experience as the prerequisite for mastery, and seeing knowledge as independent rather than contextually embedded.

Interestingly the idea of knowledge learnability as well as the process of learning may change as the degree of tacitness in an activity or practice increases. Reber (1993) examined the concept of implicit learning in his work as the process whereby knowledge is acquired largely without the involvement of top–down, conscious control. He provided examples of language acquisition and the process of socialization to illustrate the operation of implicit learning. Reber's view of the socialization process is very close to the work done in communities-of-practice research (Lave and Wenger, 1991). Reber (1993) suggested implicit learning results in tacit knowledge and indicated that not only is the learner unaware of the process of learning, the very knowledge itself is highly resistant to explication. As Reber discussed, the notion that deep, abstract knowledge can be acquired and represented outside of consciousness is close to Polanyi's original use of the term. A particularly important observation, however, is that such deep, abstract knowledge is possible to acquire through action.

The Next Iteration

Current efforts to understand the dynamics of knowledge in organizations and to gain an enhanced appreciation for what knowledge can trigger and how knowledge can be used in organizations may require a step back to help us understand and rethink what knowledge is and what the important characteristics of knowledge are within practices or activities in

organizations. This presents an exciting extension of knowledge-based views of organizations and the potential contribution of tacit knowledge to achieving desirable organizational outcomes. A realization that all knowledge has a tacit component and that learning and the learnability of that knowledge is its own unique phenomena, only begins to scratch the surface of what must be understood.

What is missing are the links between Polanyi's original work and what psychology scholars examine as knowledge that is intensely personal, introspectively opaque, and communicatively unresponsive and is acquired and used with little in the way of top–down control of consciousness. Also missing are links between the seeing knowledge as personal to an individual and the tacit elements of KIP as it is studied in organizations. How can the connections between something that is identified as so important to the success of organizations, but yet so personal in nature to an individual be studied effectively? How is individual knowledge applied and transformed in organizations and how does it aggregate from individual knowledge to collective knowledge? How can the contradictory perspectives and assumptions about what tacit knowledge is and how it influences behavior best be reconciled? Research streams examining such issues as organizational routines (Feldman and Pentland, 2003; Nelson and Winter 1982), organizational learning (Crossan and Berdrow, 2003; Crossan et al., 1999), human capital (Coff, 1997; Lepak and Snell, 1999), social capital (Levin and Cross, 2004), and relational coordination (Gittell, 2001) may offer useful insights for both capitalizing on tacit individual knowledge in organizations and for developing mechanisms for generating collective tacit understanding.

Conclusion

Virtually no one in the social sciences and specifically management research doubts the importance of knowledge to society or the existence of and the importance of a tacit dimension. Yet, little agreement exists on the mechanisms that underlie tacit knowledge, or on how to best conceptualize, use, extend, and leverage this resource. Efforts to better understand how tacit knowledge shapes what employees need to be able to do on the job, what they need to know to be able to accomplish desired activities, and how tacit knowledge contributes to strategic success suggest a number of productive research agendas. While, as Reber noted in his initial article, the future looks interesting, progress will undoubtedly require cross-disciplinary teams of researchers to sort through the complex and challenging domain of tacit knowledge.

Tactile Maps in Geography

Regina Araujo de Almeida (Vasconcellos), University of São Paulo, São Paulo, Brazil

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Maps are graphic representations of space, and they are called tactile maps when in a format to be sensed by touch. Types of tactile maps are presented, and issues related to their design, production, and use are analyzed; the role of tactile cartography in geography is also discussed. The article highlights the relevance of new digital resources and assistive technologies that introduced great changes and possibilities combining tactile images, text, and sounds. Further development toward an inclusive multisensory and multimodal cartography direct to all persons is proposed, expanding the field of tactile maps.

Introduction

Maps are essential means to collect, process, represent, and communicate geographical data. For this reason, they should be available to all persons, including ones with visual impairment. Blind people have the right to access and use graphic representations and maps in a way that images can be 'seen' also by other senses, besides vision. Among the world's 700 million people at the end of 2012, 100 million live with some form of disability, and in this group, 285 million people have visual impairment (WHO, 2012a,b). These individuals need special attention within cartography and with images in general.

Maps are graphic representations of space, and they are called tactile maps when in a format to be sensed by touch. Tactile maps have been made since ancient times, as stones set in sand. Since then, maps with raised symbols have been constructed using a wide variety of materials such as embossed paper, molded plastic, and silk-screen printed fabric. Embossed signs and Braille text have been used for 150 years in maps. Many improvements have recently occurred in the area of tactile map production and use. New computer technologies have introduced great changes and possibilities combining tactile images, text, and sounds.

Tactile cartography helps to overcome informational barriers for those who cannot see, facilitating their access to a world dominated by images. Tactile maps can also help blind users to navigate through indoor and outdoor environments and to improve their geographical knowledge. All kinds of maps and graphics should become available in tactual form, preferably with sounds and visual graphic language to really promote graphic literacy and integration of the visually impaired. Types of tactile maps are presented in this article, and the various techniques used to create them are analyzed. The design, production, dissemination, and use of tactile maps are also discussed, including new computer technologies and current research. Future research and actions should move from tactile cartography to a broader field of inclusive cartography with maps reaching all people.

Tactile Map Concept, Types, and Relevance in Geography

Maps are graphic representations of space, and as abstractions of reality, they belong to the world of images. Most maps are not available for the visually impaired person and they need to be translated to a tactual graphic language using raised symbols. Maps are called tactile maps when they are in a format that lets them to be 'seen' by touch. People acquire and develop the concept of space mainly through the eye. Visual perception is fundamental for understanding the environment. People deprived of vision, either totally or partially, depend on the other senses to gather information on the real world and its geography. Blind people learn about geographical space through direct exploration, verbal explanations, sounds, smell, gestures, models, and tactile images.

Tactile maps have raised symbols on a flat surface; they differ from models, which are three-dimensional (3D), although both are perceptible by touch. Tactual perception works with movement (kinesthetic force), feeling raised images, surfaces, and objects by moving the fingers or other body parts. This is called haptic perception and it allows visually impaired persons to explore the tangible world. Besides tactile, other terms such as tangible and raised relief maps are currently applied to the same concept; haptic has been used in relation to computer mapping and visual impairment, although the word itself precedes the era of advanced technologies.

Tactile maps have been used since Egyptian times where they first appeared as stones set in sand. Since then, many materials have been used, including wood, plaster, and even embroidery. With the invention of Braille in the mid-nineteenth century, it became possible to describe map features using a font that blind people could understand. Embossed images and Braille text have been used for 150 years in maps. Recent technology has changed tactile maps and the entire cartographic communication process, from its creation to the use of images and graphic representations. Maps are essential to navigate, to develop space perception, and to gather geospatial data and knowledge. There are two main groups of tactile maps, based on their purpose, scale, and features: orientation and mobility maps, and geographical maps.

Orientation and Mobility Maps

These maps are directed only to blind and severe low-vision people who need to be aware of the physical environment in order to navigate in space. An orientation map gives an

overview of the area. Mobility maps, as the name suggests, provide the kind of detailed information that is needed if the person is to move safely through the environment. Mobility maps show obstacles to be avoided as well as elements to use such as sidewalks or elevators. They depict indoor and outdoor environments using large-scale representations of buildings, routes, streets, transportation networks, neighborhoods, and recreation areas. Verbal maps, also called sequential maps, can replace tactile mobility maps to explain routes to blind people. Often they are used with location devices such as global positioning system (GPS), but can be combined with audio–tactile maps with very good results for navigating in space.

Geographical Maps

Geographical maps represent larger areas in much smaller scale than mobility maps. General reference maps include political and physical tactile maps, ranging from cities, states, and countries to the whole globe. Tactile topographical maps are relief models, also produced in colored plastic for the sighted user, which need adaptation for the blind by having all symbols in raised format.

Thematic maps portray qualitative and quantitative geographical information in tactile form. They show the location, pattern, and structure of geospatial data on a wide variety of themes such as population, industry, climate, and distribution of vegetation, at all scales from local and regional to global. These types of maps are important teaching resources at schools and they should be directed to all students, not only those with visual impairment. At this time of innovative digital technologies, old-fashioned tactile maps still have an important role inside the classroom. Tactile maps can be used with 3D models, with or without sounds, as motivating and interesting strategies for geography teaching.

Tactile Map Creation and Use

Much work on tactile maps has been done in the past 30 years. The International Cartographic Association (ICA) has a Commission on Maps and Graphics for Blind and Partially Sighted People (see ICA Web site, also the Conferences Proceedings). Several authors have contributed significantly to the field of tactile cartography and results have been published extensively over time (Almeida and Tsuji, 2005; Barth, 1987; Edman, 1992; Heller, 1991; Jacobson, 2007; James, 1982; Kidwell and Greer, 1973; Perkins and Gardiner, 2003; Rowell and Ungar, 2003; Schiff and Foulke, 1982; Tatham and Dodds, 1988; Vasconcellos, 1996; Wiedel, 1983; Wiedel and Groves, 1972). Koch (2012) summarizes the outcomes of this research and presents an overview of tactile cartography, from design to new digital technologies, highlighting its chronological development.

Some concepts about visual impairment and tactual perception are important to map and graphics creation and use. Whether the person acquired visual impairment or was born blind, also type and degree of visual impairment may affect the way these people read images and maps. Information and publications about map design, production, and use can be found in the suggested websites and references, including issues like scale, standardization, degree of generalization, and choice of symbols.

Tactile Map Design

The design of a tactile map involves a cartographic language with tactile symbols such as raised lines, points, and textures. Visual variables studied by J. Bertin's graphic semiology (Almeida, 2011) must be translated into tactual form to construct tactile maps. The nature of geographical data, either quantitative or qualitative, has to be considered when selecting the correct variable, whether tactile, sonic or visual, to represent the particular data element. Graphic variables directed to vision and touch (e.g., size, value, texture, color, orientation, and shape) can be expressed in point, linear, and area modes. Color is not a part of the tactual graphic language when blind persons are involved, but elevation (height) can be used alone or combined with other variables in multiple ways to represent features in addition to height of the terrain.

Clarity and simplicity are important qualities in tactile mapping, as is the use of a map legend or key. A collection of maps or a multilayered tactile map can help avoid complexity and excessive clutter, making tactual perception easier. Tactile maps when designed for low-vision users should combine visual and tactile symbols, preferably in color, but with limited variation of hues and tones. Many studies have been done on the legibility and discriminative capability of symbols from the perspective of the visually impaired as map users. In general, choice of symbols, scale, and degree of generalization greatly depend on the production method to be used, including master construction and reproduction techniques. Concepts such as generalization and standardization can facilitate design and use, but they are not easy to deal with and are still a challenge for geographers and cartographers. Orientation and mobility maps are more likely to have a system of conventions established at the international level.

The author, in previous work (Vasconcellos, 1996: 99–100) discussed tactile map production and use, and presented a set of guidelines directed to design, reproduction, map use, and education. Several authors, mentioned before, contributed greatly to tactile map design, such as Barth, Edman, Kidwell, and Greer, Tatham. Rowell and Ungar (2003) presented the results of an interesting survey that collected data on production methods, techniques, outputs, and preferences related to tactile mapping design, such as the choice of map size and format, and choice of symbols. Perkins and Gardiner (2003) also contributed to tactile map design and use with several publications; they presented a manual with best practices and guidelines for the design, production, and presentation of vacuum-formed tactile maps, which can be seen at the Perkins School Web site.

Production Methods and Materials

Many techniques and materials are used in the construction and reproduction of conventional tactile maps. The advantages and

limitations of these production methods might include, for example, cost, available technology, number of copies needed, or the user's ability to read maps. The most common methods are

1. hand-made collage maps using a large variety of inexpensive materials, usually prepared by nonspecialists;
2. molded plastic maps done in vacuum-forming machines (e.g., Thermoform with Brailon plastic), and made from a master map prepared in a variety of materials such as embossed aluminum, collage, paper, or plaster carved manually or driven by computers;
3. embossed paper maps done by Braille printing machines, using conventional or digital methods;
4. silk-screen maps using puff ink, usually printed on paper; and
5. microcapsule paper maps compatible with conventional printers and raised by heat, largely used with digital maps and computers.

Collage has very good discriminatory properties because of its varied textures, low precision, and low-cost reproduction capability. On the other hand, silk-screen and microcapsule paper maps have lower discriminatory properties, but high reproduction capabilities and they are more pleasant for touching. Besides these more common techniques, there are others such as German film, virktyping, or thermocraft. Each has its advantages and disadvantages depending on a variety of factors including available technologies and user preferences.

Tactile Map Use: The Need for Education and Training

There are some rules to be followed regarding tactile map use. In general, more training is necessary for all persons involved in tactile mapping, both producers and users, than is the case for visual maps. In addition, many tactile map creators are not geographers or cartographers and therefore need even more education and training when responsible for mapping tasks.

Before using maps, it is advisable to teach basic geographical concepts such as scale, point of view, relative positioning, orientation, location, and distance. Tactual graphic language has to be introduced to the users before tactile map reading exercises that help them to understand physical space and its representation. For this purpose, a program to teach this language for children was designed, with six phases, each one presenting relevant geographical concepts: (1) the tactile graphic language (memory game with tactile graphic variables as proposed by Graphic Semiology); (2) concept of scale, reduction, and distance (activity using dolls and cars in several sizes, 3D models, and a classroom map); (3) point of view (graphic representation of objects in vertical and horizontal views, avoiding perspective that is too abstract for blind persons); (4) location and orientation (a game called Geographical Battle with coordinates and hemispheres); (5) map reading (the complete address of the school, from classroom to the universe); (6) map legend and the combination of all previous five steps (exercise of constructing a city using tactile/visual variables in a mat with sticky pieces). Finally, different tactile maps could be read by users. This program was tested with hundreds of students and proved to be very effective with blind and low-vision children and teachers (Almeida, 2011).

After research and evaluations with 200 visually impaired children and adults, and 80 school teachers, the author proposed a methodology and a set of guidelines as presented before (Vasconcellos, 1996). Just some ideas for map use are listed below:

1. it is essential to introduce geographical concepts and cartographic language prior to map use;
2. it is advisable to create and use conventions as much as possible to facilitate graphic information reading;
3. the map key is very important for the visually impaired; they are experts in decoding a legend and it should be used even for drawings;
4. proper reduction and generalization are vital; also size and distance between signs are important because tactual perception has a different resolution and is not global, as the blind user must put together pieces of information to form the image; and
5. enough relief and contrast together with the use of redundancy help in achieving better map design with the needed clarity. Accuracy and precision very often have a secondary role. Sometimes the solution is to make a collection of maps, facilitating map reading tasks.

It is important to consider the user's degree of sensory impairment, previous experience, knowledge about the environment, and cartographic skills. Tactual sense is coarser and it works by bringing pieces together to form a map. It is different from sight, which is synthetic with high resolution. Despite some limitations, blind people can have an excellent ability to decode map keys by using both hands simultaneously, one on the legend and the other on the map. In most cases, the visually impaired user needs personal assistance or good instructions to understand the message conveyed in a tactile map. Successful cartographic communication depends on innovative approaches and efficient training since many of the problems this group may encounter in map reading differ from those identified for sighted users.

Audio–Visual–Tactile Maps and the Multisensory Approach

Technology has changed the field of cartography, opening amazing new doors and possibilities in tactile mapping. Sound, touch and vision can be easily put together to depict the physical and social environment; current technologies can already add smell, and research will find ways to include taste in the future. Visualization techniques are improving and expanding to virtual reality and 3D images to map geographical space; also remote sensing techniques now collect, process, save, represent, and update information (Almeida and Tsuji, 2005). What was just tactile cartography aimed at map users who were blind and visually impaired can now take advantage of all five senses and many innovations in telecommunications and computer technology, as proposed by the new cybercartography paradigm (Taylor, 2003, 2005, 2013).

Assistive Technologies: Devices and Techniques in Digital Cartography

Information and communication technologies have transformed the creation and use of tactile maps. People with visual impairment, being blind or low vision in any degree, will need different devices (equipment, products, and software) to translate visual images to other senses, such as touch and hearing; these devices are called assistive technology. The distinction between computer and no-computer aids and products relates to the user's visual impairment in terms of sensory replacement, augmentation, or substitution. The Perkins School has very good information on these topics. Almost all sensory substitute technologies are now computer related, although several have their origins in predigital technology, such as tactile graphics, Braille displays, voice recorders, and video cameras (see Perkins Web site). Tactile cartography must take advantage of a large variety of assistive technologies, including conventional ones such as a Braille typewriter and computer products. High-tech devices can make a real difference in tactile cartography; examples include computer screen readers, voice synthesizers, a variety of software and hardware, adapted keyboards and mouses, special glasses and cameras, GPS, mobile phones, and so on. All these assistive computer technologies are vital for persons with visual impairment, helping them to 'see' images and graphics using tactile and sound resources. Accessibility to such technologies is still a problem, however, in that about 80% of the world's visually impaired population live in developing countries and might have no access to Information and Communications Technologies (ITCs) and products adapted to persons with visual impairment. At present, these new forms of tactile maps, using multisensory and multimodal interactive formats, can reach only a minority of users.

Innovative Methods and Products in Tactile Mapping

During the last three decades, many technologies were developed to support people with visual impairment to 'see' maps through touch and sound. A tactile–audio system called NOMAD was invented by Professor Don Parkes, in Australia, in 1986. This system combined touch and sound so that a tactile map, when touched, spoke the information under the finger; environmental sounds and music could also be added. NOMAD and all the Tactile Graphics Designer (TGD) components that followed the first version of this audio–tactile device had functions allowing location, navigation, distance, scale, and a variety of different features presented in tactile format, graphics and maps combined with sounds. The audio–tactile system had interactive capability and up to three layers of information could be embedded in every information point. Effectively, an entire encyclopedia could be embedded, but computer storage and speeds were far from what is available today. Maps, spatial guidance systems, a capacity to paint in sound with frequencies changing at user defined boundaries of any shape made a virtual 3D audio–tactile surface possible; to read Braille and interact with voice recognition to questions by users were among its many features. It was translated into Portuguese, Spanish, Japanese, French, Italian, German, Swedish, Malay, and Dutch.

From the original NOMAD system, the TGD components of AudioPIX, Audio CAD, and Audio TRIP were developed and presented in journals and scientific conferences (Parkes, 1995, 1998). In 2004, the system was passed to Duxbury Systems for their use of any of the software that suited their purposes in their established market for Braille translation systems and embossed dot graphics.

A few years ago, a Talking Tactile Tablet, TTT3, with the same functions of the previous NOMAD, came into the market, manufactured by Touch Graphics. For navigation, BrailleNote GPS and various Adapted GPS devices make independent travel possible for blind people. For computer use by a blind person a screen reader that shows images on the monitor through sounds and speech are essential as is a Braille display. Texts are easily translated to sound using any voice synthesizer software combined with the screen reader, and BrailleTouch allows people to use touch screen mobile phones (typing Braille). The American Foundation for the Blind has an extensive list of products and software, including all sorts of assistive technology that helps the visually impaired person to access computers, multimedia interactive maps, and images. Very interesting are the force feedback joystick and mouse, but in terms of products and software, problems with discontinuity and market restrictions inhibit production of those items at a scale that is affordable for all users.

Several specialists have dedicated time and efforts to develop and study audio–tactile and visual mapping devices and software directed to people with visual impairment. As a blind person and also a geographer, Reginald Golledge was one of the first to experiment navigating with GPS and a laptop; he has done extensive work on this area (Golledge et al., 2005). Jacobson (2007) discussed the future of tactile cartography and presented a comprehensive list of all tactile map formats from conventional static raised line to multimodal computer interfaces, highlighting digital methods related to audio–tactile, multimedia, map-based approaches.

Rowell (2007) conducted an interesting survey that compared conventional tactile maps with new wayfinding geotechnology, asking 30 visually impaired persons to evaluate various wayfinding methods (tactile maps, new mobile technologies, audio descriptions, and fixed-electronic navigation aids). The sample individuals reported that tactile maps and GPS devices were the most useful navigation aids for blind people; several comments were made about advantages and problems, discussing the potential of these new technologies. Multisensory interactive maps do work and can change the way visually impaired persons relate to cartography, as argued before (Almeida and Tsuji, 2005).

There are many recent developments in this field where computers, telecommunications, geographical position systems, mobile phones, and tablets connected to the Internet can work together, facilitating the production of multisensory maps combining sounds, images, and tactile graphics.

Future Directions: Barriers and Opportunities in a Digital World

New technologies have introduced great changes and improvements in the area of tactile map production and use.

Tactile maps will evolve to multimodal and multisensory maps, in an interactive multimedia format as proposed by cybercartography (Taylor, 2003). The challenge for cartography will be to provide these maps and innovative resources, as well as to make them available and accessible to all users, including those with visual impairment. Conventional and old-fashioned tactile maps with Braille text will be produced and used for a while yet, but new technologies will create a totally new area in mapping for people with visual impairment, bringing new possibilities for both tactile map creators and users.

In any case, it is important to prepare these new map users to deal with cartography and audio–tactile visual resources. On the other hand, there is a need to produce and disseminate tactile graphics, especially maps, not only for the blind, but also as teaching materials for all students and schools. Education and training in tactile cartography still needs attention and further action. Tactile cartography helps to overcome informational barriers for those who cannot see, facilitating their access to a world dominated by images. Therefore, all kinds of maps and graphics should be available in tactile and interactive multisensory forms with sound, promoting graphic literacy and integration for all visually impaired people, regardless of location or social class.

Future research should move from tactile cartography to a broader field of inclusive cartography with maps reaching more people, so that multimodal maps are accessible everywhere and by everyone. From an old thermoformed or collage map to a virtual map in mobile devices using location-based services or cloud computing, all maps are relevant and they are a unique means to achieve space perception and knowledge, to communicate spatial information, to navigate, and to learn geography.

Tactile Processing

Alberto Gallace, University of Milano-Bicocca, Milan, Italy

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Tactile information processing is of vital importance for differentiating and protecting our body from the external world. At the same time, it provides a powerful means of physical and social interaction with other individuals. Not surprisingly, then, tactile processing develops and reaches full functionality well before other sensory modalities. Despite the fact that the neurocognitive mechanisms of tactile information processing are understudied with respect to the processing occurring in other senses, researchers have just started to unveil their complexity. In particular, it has been shown that in order to process touch, our brain requires the integration of information coming from different classes of tactile sensory-specific receptors, with information arising from the processing of other sensory stimuli (e.g., visual or auditory). Cognitive factors, attention, beliefs, and the physiological parameters of the organisms also enter the computation that leads to tactile perception. Even more interestingly, research has shown that tactile processing is very effective in driving our behavior in a number of different contexts. This powerful effects of touch are, at least in part, due to the role played by newly discovered tactile fibers that would seem to be related to the most pleasant aspects of our social behavior.

Introduction

Far less attention has been given by researchers to the study of tactile processing as compared to the study of information processing in other sensory modalities, such as vision and audition. This has occurred for a number of reasons, comprising the difficulties experienced in the past in stimulating tactile receptors in a controlled fashion, as well as the common view that vision is our dominant sense. The last few years have seen a renewed interest in the study of tactile processing from a number of different perspectives (see Gallace, 2012; Gallace and Spence, 2014; Hertenstein and Weiss, 2011; McGlone and Spence, 2010). Neuroscientists, psychologists, anthropologists, engineers, designers, and clinicians are now more than ever before interested in understanding the mechanisms of tactile information processing, for both theoretical and applied reasons. This new wave of interest is likely driven by a number of factors, such as the availability of devices that allow for tactile stimuli to be precisely delivered, the realization of how important touch is for our well-being, the development of multisensory virtual reality technologies, the increased use of human–machine interfaces that require active manipulation, and the need to provide more complete access to information to visually impaired individuals, just to cite a few of them (Gallace and Spence, 2014; Gallace et al., 2011a).

It is now clear that tactile information processing is of great importance in order to offer protection to the body, from both physical and psychological points of view. That is, touch provides information about potentially dangerous stimuli that get in touch with our skin, and at the same time contributes to differentiating what is 'us' from what is the outside world. However, touch not only provides a protective function to our organism but also acts as a powerful interface that allows us to interact, both socially and physically, with external stimuli. Not surprisingly, then, touch is the very first sense to develop; and a 6-week-old embryo, who is still totally blind and deaf, has already the ability to perceive tactile stimuli (e.g., Atkinson and Braddick, 1982; Bernhardt, 1987; Bremner et al., 2012). Interestingly, early tactile interactions have also been reported to occur between twin fetuses within the womb (Castiello et al., 2010). Even after birth, when the sight of the newborn still has very poor resolution, touch offers the very first means to interact with the world. In fact, the automatic hand closure response of babies to objects that are put on the palm of their hands is likely a mechanism developed for helping the newborn to determine the nature of external stimuli.

Before discussing further the mechanisms of tactile processing, it is important to make a distinction between touch and haptic perception. In particular, researchers distinguish haptic from tactile perception because the former involves the active, serial exploration of a stimulus by means of different body parts (i.e., such as when we try to look for a certain object in our pocket or in a bag without looking at it). By contrast, tactile perception can occur regardless of our movements, even when an object lays or moves on our skin surface (Lederman and Klatzky, 2009).

Neural Mechanisms of Tactile Processing

Tactile processing starts from the activation of receptors distributed throughout our skin. Different classes of receptors respond to different forms of information or energies (see Gallace and Spence, 2014; Kandel et al., 2000). The Pacinian corpuscles, found mainly on the palms of the hands and soles of the feet, respond to the mechanical deformation of the skin. The Meissner corpuscles also respond to pressure stimuli and are responsible for the higher tactile sensitivity of certain body sites as compared to others. In fact, our sensitivity to tactile information is not the same across the entire body surface. Body areas such as the fingertips and the lips have far greater sensitivities than the back or the calf (e.g., Weinstein, 1968). Other receptors respond to thermal rather than mechanical information. That is, 'thermoreceptors' code absolute and relative changes in temperature within a nonpainful range (e.g., Darian-Smith et al., 1979; Schepers and Ringkamp, 2010). Certain receptors, such as the hair root plexuses, are wrapped around our hair roots and can detect

movements on the skin surface that disturb the hairs (e.g., Kandel et al., 2000; Purves et al., 2004). Importantly, receptors differ not only in terms of the form of energy that they are capable of transducing but also in terms of their pattern of response. In particular, fast-adapting receptors fire for only a few milliseconds after the presentation of a stimulus on the skin, and then they become silent. By contrast, slowly adapting receptors keep responding until the stimulus is removed from the skin (e.g., Birznieks et al., 2009).

It is important to mention here that even if tactile receptors specialize in transducing energies that are interpreted by our brain as tactile stimuli, their activation is not always necessary or sufficient to elicit specific tactile percepts. That is, it is now well established that people can sometimes mislocalize tactile sensation toward regions of space where there are no receptors or sometimes not even a body surface (see Gallace and Spence, 2014, for a review). Tactile sensory illusions as well as tactile hallucinations (e.g., 'delusional parasitosis,' where people perceive crawling sensations on their body) have also been extensively reported by researchers in this field (e.g., Hayward, 2008; Huber et al., 2008; Musalek et al., 1989). Moreover, what we commonly call 'touch' is actually the final product of the interactions occurring among information coming to the brain from different classes of peripheral receptors (see Berkley and Hubscher, 1995; Iggo, 1977; McGlone and Reilly, 2010). For example, certain sensations, such as those of wetness (given by the activation of both mechanoreceptors and thermoreceptors) or of tickle (produced by the common activation of the free nerve endings and the Pacinian corpuscles), are the consequence of the multisensory interactions occurring in the brain. That is, no dedicated receptor in our skin is specialized for coding wet or tickling stimuli.

Different brain areas are responsible for the processing of tactile information. In particular, the primary somatosensory cortex (SI) of the brain receives afferent stimuli from each part of our body, so that different areas within this structure represent tactile stimuli originating from specific body regions. By analyzing the responses of the somatosensory cortex to stimuli delivered to our skin, it is therefore possible to obtain a complete neural representation of the body, known as the 'homunculus man' (or, as some have renamed it, the 'hermunculus' when referring to the female body; Di Noto et al., 2012; Penfield and Rasmussen, 1950). This representation in our brain does not fully match the physical structure of the body, but it depends on the amount of neural fibers and receptors that innervate different body parts. For example, within the homunculus, the representation of the face is larger than the representation of the arm, the face being a body part that is innervated by a higher number of neural fibers (and thus more sensitive to touch) than the arm. The left primary somatosensory cortex responds only to stimuli presented on the right side of the body, while the right primary somatosensory cortex responds to stimuli coming from the left body side. Another important area in tactile processing is the secondary somatosensory cortex (SII), where information coming from different body parts is integrated. That is, there is now ample evidence showing that representations posterior to SI, such as those in SII, receive inputs from both body sides (e.g., Blatow et al., 2007; Ferretti et al., 2003).

Higher Order Processing of Tactile Information and Tactile Awareness

Most of the information that is processed by our brain does not enter our awareness, and this is certainly true also for tactile sensations. For example, tactile signals are continuously used by our neural system in order to control our posture when we sit or walk, but we are not constantly aware of the presence of the chair or the floor behind our body (at least if we do not explicitly attend to them). The relevance of this automatic, and mostly unaware, processing for our daily life becomes apparent only when we observe the behavior of those patients who lost their ability to perceive tactile and proprioceptive (information regarding the position of our body parts in space) signals coming from their body, due to certain forms of illness. As this quote clearly suggests, for these patients even apparently simple daily activities such as sitting, walking, or feeding become a huge challenge (e.g., Cole and Paillard, 1995):

> Speaking and chewing were almost impossible, and for several months she existed solely on pureed food. Then she became so exasperated by this that she began to experiment in eating. She learned to push food to one side of the mouth, chew a certain number of times, and then push the food to the back of her mouth and swallow it automatically. Facial expression was severely limited because of the absence of proprioception from the lower face. She refused to look in a mirror for two years after the illness. For a similar time, she had to remember to concentrate to keep her mouth from opening. (From Cole and Paillard, 1995: p. 249)

Despite the amount of implicit processing of tactile information occurring in our brain, there are situations where becoming aware of tactile stimuli becomes really important. This typically occurs when new or potentially relevant stimuli get in touch with (or are removed from) our body surface. That is, while it is not relevant for us to be constantly aware of the presence of the chair where we sit, perceiving that someone or something has suddenly touched our shoulder is often relevant. An unexpected change in the status in our tactile environment certainly requires awareness. Surprisingly, however, also potentially relevant information often goes unnoticed. Those who have been pickpocketed at least once in their life certainly know too well how easy it is to fail to perceive that something is happening somewhere on our body! Laboratory studies have shown that the presence of distractors, whether tactile or visual, as well as of a discontinuity in the flow of tactile information can easily lead to the failure to perceive tactile changes on our skin (a phenomenon that is known as 'change numbness' and that also has been shown to occur in visual perception – where it is known as 'change blindness'; Gallace et al., 2006; Simons and Rensink, 2005). This phenomenon is thought to be due to the competition between multiple sources of information for accessing processing (i.e., cognitive or attentional) resources in our brain (e.g., Simons and Rensink, 2005).

As far as the neural mechanisms of tactile awareness are concerned, ample evidence now suggests that tactile processing occurring in SI (discussed in this article) is necessary, but not sufficient, for the awareness of tactile sensations to occur (Gallace and Spence, 2010b). In particular, magnetic imaging

on human patients who reported a lack of somatosensory sensations revealed the presence of early neural activations in the primary somatosensory cortex, but the absence of any later activation in higher order brain areas (Preissl et al., 2001). Similarly, a study on neurologically normal participants showed that early brain activity generated in the somatosensory cortex contralateral to the stimulated region of the body was uncorrelated with the perception of the stimulus. By contrast, later activity in parietal and frontal areas was observed for consciously perceived target stimuli (Palva et al., 2005).

Interestingly, studies on patients affected by brain damage have shown that a correct localization of tactile stimuli can be performed despite a lack of awareness regarding the presence of the stimuli (e.g., Brochier et al., 1994; Imanaka et al., 2002; Rossetti et al., 2001). For example, Brochier et al. (1994) described a patient who, as a consequence of damage to his right primary somatosensory cortex, lost tactile sensitivity in his left arm but was able to point correctly to stimulated locations on his limb when blindfolded. That is, the ability to process spatial information regarding the position of tactile stimuli, carried on by higher order parietal brain areas, is not sufficient to lead to awareness of tactile information. On the basis of these different observations, it has been suggested that in order for awareness of touch to occur, tactile processing needs to be supported by complex brain networks likely involving sensory-specific areas (such as SI), as well as higher order associative brain areas (e.g., the posterior parietal cortex, the insular cortex, and the prefrontal cortex; e.g., Gallace and Spence, 2010b).

Social Aspects of Tactile Processing

Despite of the importance of social interactions in our life, their tactile aspects have been studied very little by researchers very little (see Gallace and Spence, 2010a; Hertenstein et al., 2006). However, the few studies that have addressed the role of tactile processing within this domain have found surprisingly interesting results. In particular, it has been shown that tactile social interactions, even if unnoticed or irrelevant to the context where they occur, have a very powerful effect on a person's evaluation of a given situation or in eliciting certain kinds of behavior. For example, people have been shown to be more compliant to a request when they are touched by another person than when they are not touched (a phenomenon known as the 'Midas touch effect'; e.g., Crusco and Wetzel, 1984). However, within certain contexts, touch can also have negative consequences on our behavior or judgments. For example, Martin (2012) reported that people who were touched by another customer when examining products in a store evaluated the brands more negatively than those who were not touched.

One of the most promising fields of investigation within research on social touch is likely related to the discovery in humans of a new class of tactile fibers, known as C-Tactile (CT) afferents (e.g., see Löken et al., 2009; McGlone and Spence, 2010). These fibers, found in the hairy but not in the glabrous skin, respond best when the skin is stroked at a speed of about 1–10 cm s^{-1}, a stimulation that resembles a caress (e.g., Bessou et al., 1971; Iggo, 1977; Olausson et al., 2008). That is, these fibers would seem to be associated with the perception of the more pleasant aspects of tactile stimulation. It has even been suggested that the CT fibers are part of a neural system responsible of the maintenance of physical and social well-being in humans (Björnsdotter et al., 2010).

The presence of CT fibers in humans is certainly relevant proof of the importance played by tactile processing in affiliative social interactions. This crucial role of tactile interactions in our social behavior is also supported by a number of studies on couples. In particular, it has been reported that women who received physical partner contact before a stressful situation exhibited significantly lower cortisol and heart rate responses to stress (e.g., Ditzen et al., 2007).

It is important to mention here that many effects of social touch on behavior and physiological responses are likely mediated by hormonal mechanisms. In fact, it has been demonstrated that tactile stimulation, whether sexual or nonsexual, induces the release of oxytocin (Shermer, 2004; Williams et al., 1992), a hormone implicated in human and animal bonding behavior (e.g., Bales and Carter, 2003). Interestingly, the relationship between tactile processing and hormone release would seem to be a two-way one. That is, touch certainly affects the release of hormones, but also the perception of touch can be affected by hormones. For example, during the refractory period (the period of time immediately after orgasm), men experience tactile hypersensitivity in the glans of the penis (Yilmaz and Aksu, 2000). This sudden change in sensitivity results in tactile stimuli being perceived as aversive, and seems to be related to the release of prolactin that follows the orgasm (Krüger et al., 2003).

The Contribution of Tactile Processing to the Representation of the Body

Tactile processing not only contributes to the perception of external stimuli but also plays a major role in differentiating our body from the rest of the world. Even if we often take for granted that we have a body and that this body is ours and nobody else's, our brain actually needs to activate specific mechanisms in order to support this perception of ownership. As a matter of fact, in order to correctly perform actions within the environment, at every instant our neural system needs to establish what is our body and where it is in space. This task is achieved mostly automatically, by combining tactile, proprioceptive, and visual information regarding the body and the space around it.

Evidence of the presence of a close relationship between our body and tactile processing comes from those studies that have investigated the role of body posture on tactile perception. For example, it has been shown that it takes more time to determine the order of two sequential stimuli presented on the hand when these are positioned far apart rather than close together (e.g., Gallace and Spence, 2005; Shore et al., 2002). Similarly, tactile (as well as noxious) stimuli are perceived as less intense and require more time to be localized when the arms are crossed over the midline, rather than when they are kept parallel (e.g., Gallace et al., 2011b). That is, the processing

of tactile information cannot be fully separated from the processing of information regarding the current status of the body (i.e., in terms of its spatial position).

A large and fast-growing body of evidence unequivocally shows that people can perceive tactile stimuli as originating from spatial positions where the body is not physically present, such as from a rubber hand or even from a mannequin (e.g., Botvinick and Cohen, 1998; Petkova and Ehrsson, 2008). This is achieved by delivering synchronous visuo-tactile signals that, after being interpreted by the brain, lead to a mislocalization of the veridical position of the body. For example, in the rubber hand illusion a fake hand is stroked synchronously with the participant's hidden real hand. After a few seconds, the participant starts to claim that tactile stimuli come from the position occupied by the rubber hand rather than from their real hand. If required to point toward their hidden hand, the participants point toward a position that lies between the real and the rubber hand (e.g., Botvinick and Cohen, 1998; Tsakiris and Haggard, 2005). It has also been shown that this illusion leads to a temporary thermoregulatory dysfunction (a drop in skin temperature) of the hand that is replaced by its rubber equivalent (Moseley et al., 2008). Importantly, the visual similarities between the rubber hand and the participant's real hand do not seem to play a role in terms of inducing the illusion (e.g., Hohwy and Paton, 2010; Farmer et al., 2012).

Multisensory Aspects of Tactile Processing

The phenomenon of the rubber hand illusion clearly suggests that the integration of visual and tactile information is vital for sustaining a coherent representation of our body. However, more in general, the presence of this illusion is also suggestive of the fact that tactile processing affects and is affected by the processing of information coming from other sensory modalities in our brain. As far as this point is concerned, it has often been reported that visual information dominates over tactile or auditory information (e.g., Bertelson and de Gelder, 2004; Rock and Harris, 1967). For example, Hartcher O'Brien et al. (2008) asked their participants to discriminate between unimodal visual, unimodal tactile, and bimodal (visual and tactile) stimuli. They found that the participants failed to respond to touch far more often than they failed to respond to vision on the bimodal trials. That is, the simultaneous presence of visual stimuli often extinguished the perception of tactile information.

Besides the studies that have shown visual dominance over touch, there are also examples suggesting that even touch, under certain conditions of stimulus presentation, can affect the perception of information coming from other sensory systems. For example, tactile cues often dominate over visual cues when judging attributes such as an object's temperature (e.g., Bushnell et al., 1985) or its fine surface texture (e.g., Guest et al., 2002). Similarly, Violentyev et al. (2005) found that participants report the presence of two flashes when only one was produced, if two tactile taps were delivered within a 60 ms interval. As a consequence of these observations, as well as of similar observations made on different couples of sensory modalities, it has been suggested that there is not a single sensory modality that always dominates over the others. By contrast, under conditions of multisensory stimulus presentation, the sensory modality that carries the lowest variance (i.e., noise) in a person's estimate regarding a given quality of a stimulus is the one that will likely 'drive' the processing of the inputs provided by the other senses (e.g., Ernst and Banks, 2002; Ernst and Bülthoff, 2004).

When one considers all of the factors that seem to affect tactile information processing, it should be mentioned that not only stimuli from other sensory modalities are able to drive our perception of touch, but also cognitive factors and beliefs are equally effective (e.g., Kress et al., 2012). For example, it has been demonstrated that people's evaluation of the very same tactile stimulation changed as a function of the gender of the person who was thought to deliver the stimuli (Gazzola et al., 2012). That is, somewhat unsurprisingly, it has been demonstrated that heterosexual males evaluate tactile stimuli as less pleasant when they believe that the stimulation was delivered by a man wearing a tracksuit, as compared to when they perceive that the stimuli are delivered by a woman wearing a black evening dress and high heels. However, the most interesting aspect of this study is perhaps that not only the evaluation of the stimuli but also the neural activations elicited by them were affected by the participant's beliefs. Specifically, the activity of SI, an area thought to be primarily involved in processing the more perceptual aspects of tactile stimuli (rather than their hedonic value), was modulated by the visually perceived gender of the caresser.

Conclusions

Tactile processing has certainly been less studied as compared to visual or auditory information processing. Despite this, scientific research within this domain is quickly moving and has just started to unveil how relevant tactile stimulations are for our survival and well-being. It is now clear that tactile processing contributes to supporting our sense of body ownership, as well as our ability to perform even the simplest movements. Tactile information processing is affected by other signals that are concurrently processed by the brain. In particular, stimuli from other sensory modalities, cognitive factors, beliefs, attention, and certain physiological parameters of the body (comprising the hormonal levels) are all able to drive our interpretation of (and response to) the stimuli that get in touch with our skin. Similarly, the processing of tactile stimuli can efficiently modulate our brain responses to other sources of information.

Tactile processing is likely to become an even more important research topic in the future, given its relevance to the development of modern technologies and product design. In fact, an increasing number of everyday objects, from touch screens to food packaging, in order to be fully appreciated by the consumer need to capitalize on our knowledge of the neurocognitive mechanisms supporting tactile information processing (e.g., Gallace and Spence, 2014; Spence and Gallace, 2011).

Abstract

Learning happens for human being mostly through physical, cognitive, and emotional interactions with the external environment. With the aid of information technology, interactions have gone beyond the limit of working on a desktop computer, using a mouse and keyboard to interact with windows, icons, menus, and pointers, in which tangible user interface (TUI) is gaining increasing attention. This article will provide an overview of TUI, discuss its functional characteristics, present some application cases, and discuss design and application issues for TUI in education.

Tangible user interface (TUI) is a user interface in which a person interacts with digital information through the physical environment (Roebuck, 2011). TUI aims to interlink the digital world and physical world seamlessly so as to allow humans to acquire knowledge of the world around them through holistic interactions with their external environment.

Tangible User Interface

How can human beings learn by taking the most advantage of interactions with the environment? In decades, with the fast development of information technology, the computer has become the critical part of what people interact with. However, sitting in front of the screen, hearing through earphone, moving mouse, and clicking keyboard have isolated humans from the physical world. In *Back to the Real World* (1993), the authors argued that both desktop computers and virtual reality are keeping human away from 'natural world'. Therefore people should augment and enrich the real world with digital technology, thereby transiting from the real world to the digital world fluidly without the cost of losing physical touch. Papert at the MIT Media Lab pioneered in making the use of computers for 'thinking about thinking' in embedded programs. Such project (e.g., LEGO/Logo) allows children to become the designers and creators of their physical interactive machines (e.g., robots, motorized cars, motion detectors, and various other simple digital transducers). Following development in an initiative interaction style is the notion of a graspable user interface (GUI) introduced by Fitzmaurice et al. (1995), where graspable handles made of wooded blocks are used to manipulate digital objects to increase the directness and manipulability of graphical user interfaces. However, GUIs fall short of embracing the richness of human senses and skills (Ishii and Ullmer, 1997). Transition from 'painted bits' to 'tangible bits' is further developed by Ishii and his research group. They use tangible objects rather than graphical blocks to manipulate and represent digital content by developing TUI prototypes named Geospace and Urp. TUI interaction model surpasses GUI's remote control of digital information and invites users to manipulate their physical world.

TUI Interaction Model

Input and output or control and representation are paired concepts in such interaction. Figure 1 describes the interactive relationship between human and digital information through inputting for control and getting output. According to the basic model, Ishii puts forward GUI and TUI models as shown in Figures 2 and 3.

As Figure 2 shows, in the GUI model, computer input and output are separated, because input is obtained from control 'peripherals' such as the keyboard and mouse and the output is delivered in the form of 'digital representations' such as screen-based graphics and text, or speakerphone. In other words, there is a separation between graphical representation and control. Whereas, TUI model (Figure 3) integrates physical representation with control by physically embodying the input and output in the interface that allows users to manually manipulate objects.

Characteristics of TUI

Representation is a keyword in tangible interaction and has a broad meaning. In general, there are internal representation and external representation: the former refers to a presentation to the mind in the form of an idea or image in cognitive process, or the programs and structures in computer process; the latter refers to the external manifestations of information

Figure 1 User interface model. Reproduced from Ullmer, B., Ishii, H., 2001. Emerging frameworks for tangible user interfaces. In: Carroll, J.M. (Ed.), Human-computer Interaction in the New Millennium. Addison-Wesley Publishing, Reading, MA, pp. 579–601.

Figure 2 Graspable user interface interaction model. Reproduced from Ullmer, B., Ishii, H., 2001. Emerging frameworks for tangible user interfaces. In: Carroll, J.M. (Ed.), Human-computer Interaction in the New Millennium. Addison-Wesley Publishing, Reading, MA, pp. 579–601.

Figure 3 Tangible user interface interaction model. Reproduced from Ullmer, B., Ishii, H., 2001. Emerging frameworks for tangible user interfaces. In: Carroll, J.M. (Ed.), Human-computer Interaction in the New Millennium. Addison-Wesley Publishing, Reading, MA, pp. 579–601.

in fashions directly perceivable by the human senses. Ullmer and Ishii (2001) divide the space of external representations into two broad classes: physical representations and digital representation. Physical representation is physically embodied in concrete and tangible forms, while digital representation is digitally expressed to be computed and mediated in the computer system, thus intangible in form. For instance, the pictures on a screen or audio from a speaker are examples of digital representations, while physical abacus is an example of physical representation. The tangible interfaces are products of a careful balance between these two forms of representation.

Tangible interaction aims to seamlessly integrate the representation and control and thereby shows four properties:

- Tangible objects are coupled with digital data through computerized functionality.
- Manual interaction with tangible objects: the tangible objects embody the means of interactive control by allowing user to manipulate objects.
- The tangible objects are perceptually coupled with digitally produced representation.
- The state of the tangible objects embodies core aspects of the entire system's state (representational significance), and the system is thus at least partially legible if power is cut.

The Classification of TUIs

Ullmer et al. (2005) identify several main types of TUIs: interactive surfaces, constructive assembly, and token + constraint. Other researchers are now investigating additional kinds of systems. Slotta et al. (2013) recognized the following three types of TUI applications: immersive environments, embedded phenomena, and augmented reality (AR). Together, these perspectives cover most existing applications. Each is summarized in the list below:

- Interactive surface. The tangible objects are manipulated by users on planar surfaces in terms of arranging the location of objects and exploring their relations (e.g., the order of the placement).
- Constructive assembly. Users can handle modular and connectable factors to make meaningful objects. Unlike interactive surface, this tangible type enables users to spatially organize the modular and connectors and see the result of different orders.
- Token + Constraint system. Digital and physical objects are combined together. A token is a graspable object that embodies digital information and computation in the system that allows users to interact with either digital information or digital function. Constraint is an object that limits the properties and behavior of a token to which it is attached. It constrains a token's behavior in three ways: the way, limitation for interaction space, and reference frame for users to interact with a token + constraint system.
- Immersive virtual environments are virtual environment systems that amplify the effect of simulation by surrounding the user with numerous layers of sensory and perceptual information created by digital devices (Loomis et al., 1999). Not every immersive environment is an example of tangible interactions. Some, like immersive gaming environments, are purely digital; others, however, have been developed to promote an active, physical, or embodied interaction with the immersive environment. Below, we review the EvoRoom project, a room-sized immersive simulation environment where students and teachers interact physically with their surrounding media and their peers.
- Augmented reality. AR is a medium in which digital information is added to the physical world in registration with the world, and the information displayed depends on the location of the real world and the physical perspective of the users in physical world. In AR, users can interact with the mixed reality in different levels from simply changing the physical perspective (e.g., seeing it from a different point of view) to manipulating and even creating new information (Azuma, 1997).
- Embedded phenomenon is a learning technology framework in which simulated scientific phenomenon are mapped onto the physical space of classrooms. Students monitor

and control the local state of the simulation through distributed media positioned around the room, gathering and aggregating evidence to solve problems or answer questions related to those phenomena (Moher, 2006).

Above categories provide the continuum of TUI from manipulative to environment, and some have intertwined meaning, such as immersive environment and embedded phenomena, with commonality in using simulated reality. However, immersive environment emphasizes the involvement of user by seeing, hearing, sensing the environment, while embedded phenomenon makes innovative use of space and time in classroom for students by creating multiple natural representation in classroom and providing persistent experience for them to probe multiple vantage points.

Application Cases of TUI in Education

There is a lack of established theoretical or empirical base for how to design tangible interfaces for learning. Instead, designers can learn from successful cases in educational and related studies, as described in the following section.

Interactive Surface

For interactive surface, users are able to manipulate the tangible objects on a surface or move themselves on the surface to interact with the digitalized location and explore the relations of the order or place of the placement. Physical intervention in computational optimization (PICO) (Patten and Ishii, 2007) is such a digital surface TUI that can allow users to track and move small objects on the surface and learn from the changing variables represented by the positions of objects. A study on comparing PICO with two alternative interfaces without actuation showed that participants are better in solving a complex spatial layout problem using PICO system.

Constructive Assembly

In constructive assembly system, users can handle modular and connectable factors to make meaningful objects. Topobo is a 3D constructive assembly system for kinetic knowledge learning with model making and playing mechanics. By snapping together a combination of passive (static) and active (motorized) components, users can quickly assemble dynamic biomorphic forms such as animals or skeletons with Topobo, and activate the forms by operations such as pushing, pulling, and twisting the objects (Raffle et al., 2004). The evaluation of Topobo showed that it can help children understand certain physical principles affecting kinematic systems, and learn about the fields of modular robotics, system coordination, emergent dynamics, and locomotion. Topobo makes complex knowledge concrete by allowing users to assemble models embodying computing process and kinetic principles.

Token + Constraint System

Digital and physical objects are combined together by allowing users to manipulate tokens within the frame of constraint. Ullmer et al. (2005) developed two tangible query interface prototypes with tokens to represent database parameters upon physical constraints such as tracks and slots. User could learn database queries, views, and Boolean operation by manipulating the tokens on the constraints. However, the study showed that it was not better than traditional GUI in terms of database query learning achievement.

Immersive Environments

EvoRoom (http://encorelab.org/projects/evoroom/) is an immersive, smart classroom project where a room is turned into an 'immersive experience' – on all the walls, a simulation of a rain forest is projected, which makes users feel like standing in a rain forest environment. There are also rich audio and supplemental ambient features (like mosquito nets or potted plants) to achieve the feeling of immersivity. Students walk around the room, each with their own assignments, to achieve a scientific learning goal. They use tablet computers to make observations.

Augmented Reality

AR is an important type where information is mapped onto the physical environment, with extra layers of information allowing the learner to gain personally or contextually relevant information. Ambient Wood is an outdoor playful AR project in which pervasive technologies are used to digitally augment a woodland in a contextually relevant way, enhancing the 'usual' physical experience available to children exploring the outdoor world. Studies reveal that AR can be a highly engaging novel experience for learners. It can effectively support collaborative learning and provide preliminary guidelines for designing different ways of delivering digital information for learning.

Embedded Phenomenon

Embedded phenomenon is rather a learning technology framework than technology, in which simulated phenomena are projected onto the physical space of classrooms. Students monitor and control local state of the simulation through distributed media located around the classroom, so as to directly gather data for problem solving related to these phenomena (Moher, 2006).

A relatively mature project is RoomQuake developed by Moher and his colleagues. The classroom is a simulation system of active seismic field where a series of earthquakes is anticipated over the course of several weeks. Ambient media function as simulated seismographs that depict continuous strip chart recordings of local vibration where locality is decided by specific placement in the classroom. When simulated earthquake happens (increasing rumble), students move to the seismographic station to read the waveforms that signal the level of the vibration. The seismogram recorded provides two important pieces of information: the magnitude of the event and the distance of the event from the recording station. Students could collect several sets of data and then determine the epicenter. Two trial studies on RoomQuake show that

students' competence grew during both trials in terms of articulated skills related to explaining seismogram and understanding of event distributions. Although students could find solution by trilateration, the transformation from this physical skill to paper work is less successful, with only 40–60% of students being able to construct or select a proper rationale. Moreover, a pre–post comparison with a nontreatment group confirmed a significant learning effect associated with preunit conception.

While above application cases emphasize different tangible types (e.g., interactive surface, token manipulation, assembly, immersion, or AR), the commonality among them is to construct at-hand experience with external representation for body to regulate, constrain, and distribute cognition (Moher, 2006). With the ongoing manipulation of objects, students interact with the environment with their body, emotion, and cognition, so as to know the forthcoming and invisible principles that are not easy to grasp through abstract thinking.

Design of TUI in Education

Learners in the TUI environment are expected to engage physically, cognitively, and emotionally in learning tasks. However, how to design engaged learning in TUI is still new to many teachers. In order to fill in this gap, the Cybergogy model developed by Wang and Kang (2006) is a synthesis of current thinking of engaged learning from cognitive, social, and emotional aspects. Here we revise this model by adding the physical dimension (Figure 4).

Therefore, the TUI design model has four overlapping domains: cognitive, emotive, physical, and social. In order to effectively engage in learning, students must have the prior knowledge, be motivated to learn, and be comfortable with the learning environment in terms of social commitment, communication, involvement, and physical surroundings. For the physical dimension, learning environment is expected to provide learners with proper simulation, suitable tangible type, interactive scenario, and spatial arrangement. With this model, teachers or researchers could assess students' needs and attributes (Wang and Kang, 2006), detect students' emotional cues, and cultivate their positive feelings, so to increase their emotional engagement in learning. Similarly, to address students' cognitive need, they can also design related tangible type with specific physical interactive interface and simulation based on necessary spatial arrangement.

Challenge of TUIs in Education

While theory and application of TUI provide tentative evidence and possibility in learning, the application of TUI in education is still in its infancy. With the advantages of sensory engagement, accessibility to various students, and encouraging student to take part in group learning, comparative studies with traditional interactive learning environment also have positive

Figure 4 Learning design model in TUI. Revised from Cybergogy for Engaged Learning proposed by Wang and Kang.

learning effect at the aspects of cognition, motivation, and perception, and even abstract problem solving.

However, caution should be given to the limitation of TUI.

> Such systems require a careful balance between physical and graphical expression to avoid physical clutter, and to take advantage of the contrasting strengths of different representational forms. This balance between physical and digital representations stands as one of TUI's greatest design challenges.
> (Ullmer and Ishii, 2001: p. 600)

Scalability

Scalability is one of the biggest challenges for people who design and develop TUIs (Shaer and Hornecker, 2010). Digital representation may just have several lines code, while the mechanic to turn it into physical representation is not easy in terms of space, revision of model, and coupling the digital and physical representation in complex form.

Malleability

Malleability is another challenge because physical objects are rigid and static in comparison with digital objects that are malleable, easy to create, modify, replicate, and distribute (Shaer and Hornecker, 2010). Some technologies to meet the malleable input may be helpful, such as electrophoretic ink and shape changing materials that offer rapid form if combined with computational feedback. As for application in classroom, instructional context, participation, and affective impact on learners should be taken into consideration.

Instructional Context

In TUI, environment is a mixed context with virtual and physical representation, where there are no prescribed specific instructional sequences or materials, but students are expected to design, adapt, and construct the activity flow, maybe with scaffolding from teachers. To some degree, students are socialized in the context, and the appropriateness with proper balances should have multiple choices to meet individual need from students. In Moher's study, teachers helped much in exploring instructional contexts. For example, students' work should have the opportunity to be as visible as the phenomenon themselves. Large posters in subsequent classroom help to maintain the 'thread' of the ongoing activity and keep attention focused on the accumulating empirical evidence. Another contribution is that teachers' knowledge of individual students and how their learning activity should be organized and coordinated within the social fabric of the class (Moher, 2006). Teacher should make balances between choice and responsibility, skills and challenges, freedom and discipline, body and mind, and ensure productive team partnerships, whole class involvement, and individual scaffolding that are essential to learning.

Participation

Although TUI invites students to engage in interaction with the environment by allowing them to move and manipulate objects, the instructional decisions about the duration, space, and the challenges of tasks require careful planning and on-site negotiation with ongoing activities (Moher, 2006). The quality and the duration of engagement are determined by the design and scaffolding of the TUI application in classroom.

Student Adjustment

Although most of studies (e.g., Moher, 2006; Slotta et al., 2013) have positive feedback in terms of cognition and affection, interaction with TUI tends to require larger and different movements and manipulation than traditional mouse–keyboard interaction. Moreover, physical size of the students in relation to interaction surface determines reach. For students who are used to traditional interactions, both the interaction style and the effort needed to satisfy involvement are new challenges. Whether students feel comfortable and competent determines the learning process and result.

Integration with Curriculum

It is hard for designers and users to integrate TUI into the current fast-changing curriculum, since the physical representation, to some degree, is static and not easy to modify. Although the targets of a number of TUIs are to foster students' science literacy to investigate scientific knowledge with evidence-based learning, integration with frontline curriculum and practice is critical for its legitimacy.

Discussion

Because TUI is still an emerging and evolving field of research, its theory and practice are not sufficiently established for real applications. However, seamlessly integrating physical world and digital world is definitely a goal for digital natives or immigrants nowadays, when digital world tends to deprive people of interactions with the physical world. From emerging cognitive development (i.e., embodied cognition), TUIs gain the basic supporting points that mind is just partial for and determined by body which has richer sphere than mind to interact with the environment.

Although development in ubiquitous computing and AR has given promising technical supports for TUIs, another question is likely to arise: whether we will be smarter and closer to authentic environment, or we should tailor the environment to meet our infinite needs? The balance between adjustment and preservation, physical and digital, and human and nature is an old but unsolved problem.

How to use TUI in education? And how to engage student holistically in environment? In this article, we tend to address these questions through real cases. However, most studies of TUIs tend to be lab-based, having subjects interact with the system for a short time period, or take the form of field study. Such studies provide researchers with invaluable information about the positive affective feedback, and initial attractiveness of the system compared with alternatives. In addition, these studies will raise more questions that require further study. Based on the Cybergogy model, we propose a revised instructional design model to involve students physically, cognitively,

and emotionally in learning environments. Its application in education still needs further research, which will answer the following questions:

What will we expect students to learn in TUIs and how to assess it?
How will designers balance the body and mind in TUIs?
How will students adapt to TUIs?
How will teachers adjust themselves to the challenge?

Tackling these questions will be critical for showing the practical value and feasibility of TUIs.

Abstract

There are five types of taste receptor cell, sweet, salt, bitter, sour, and umami (protein taste). There are 1000 olfactory receptor genes each specifying a different type of receptor each for a set of odors. Tastes are primary, unlearned, rewards and punishers, and are important in emotion. Pheromones and some other olfactory stimuli are primary reinforcers, but for many odors the reward value is learned by stimulus–reinforcer association learning. The primary taste cortex in the anterior insula provides separate and combined representations of the taste, temperature, and texture (including fat texture) of food in the mouth independently of hunger and thus of reward value and pleasantness. One synapse on, in the orbitofrontal cortex, these sensory inputs are for some neurons combined by learning with olfactory and visual inputs, and these neurons encode food reward value in that they only respond to food when hungry, and in that activations correlate with subjective pleasantness. Cognitive factors, including word-level descriptions, and attention, modulate the representation of the reward value of taste, odor, and flavor in the orbitofrontal cortex and a region to which it projects, the anterior cingulate cortex. Further, there are individual differences in the representation of the reward value of food in the orbitofrontal cortex. Overeating and obesity are related in many cases to an increased reward value of the sensory inputs produced by foods, and their modulation by cognition and attention that override existing satiety signals.

Rapid advances have been made recently in understanding the receptors for taste and smell, the neural systems for taste and smell, the separation of sensory from hedonic processing of taste and smell, and how taste and smell and also the texture of food are important in the palatability of food and appetite control. Emphasis is placed on these advances.

Taste and Olfactory Receptors

Taste receptors. There are receptors on the tongue for sweet, salt, bitter, sour, and the fifth taste, umami as exemplified by monosodium glutamate (Chandrashekar et al., 2006; Chaudhari and Roper, 2010). Umami taste is found in a diversity of foods rich in glutamate like fish, meat, human mothers' milk, tomatoes and some vegetables, and is enhanced by some ribonucleotides (including inosine and guanosine nucleotides), which are present in, for example, meat and some fish. The mixture of these umami components, which act synergistically at the receptor, underlies the rich taste characteristic of many cuisines (Rolls, 2009).

Olfactory receptors. There are approximately 1000 different types of odor receptor each coded for by a different gene (Buck and Bargmann, 2013). This is a significant proportion of the total number of genes in humans, which is in the order of 30 000. This is a simple but genetically expensive way to build specificity into a sensory system. In humans, only approximately one-third of these receptor types are used, with stop codes in the majority of the olfactory receptor genes. This may reflect the greater reliance of primates including humans on stimuli in other sensory modalities, especially vision and hearing.

In addition to this main olfactory system using the main olfactory epithelium and its connections to the main olfactory bulb, there is an accessory olfactory system with its peripheral receptors located in the vomeronasal organ (VNO), which projects to the accessory olfactory bulb. This system is involved in the detection of pheromones, present, for example, in urinary volatiles, which are used for mate attraction, territory marking, etc (Wyatt, 2014). The VNOs of humans and Old World monkeys are nonfunctional, although pheromones or pheromone-like substances acting through the main olfactory system may be involved in social and reproductive behavior in these species.

Taste, Smell, Reward, and Emotion

Emotions can be defined as states elicited by rewards and punishers (Rolls, 2014). A reward is any stimulus or event for which an animal (and that includes humans) will work for (i.e., learn and perform an action instrumental in obtaining the reward), and a punisher is any stimulus or event that an animal to work to escape from or avoid. All tastes are primary, unlearned, reinforcers. For example, animals show that a sweet taste (if hungry) and a salt taste (if salt deprived) are rewards the first time that taste is made available. Animals will similarly reject bitter tastes (which are generally produced by plants for exactly that function). Taste is thus very important in emotion, for it serves as an unlearned reward or punisher. Other primary reinforcers include soft pleasant touch, and pain, with many other examples provided in *Emotion and Decision-Making Explained* (Rolls, 2014).

Emotions, as states elicited by instrumental reinforcers (e.g., a warm pleasant feeling produced by a soft caressing touch), can thus be seen to provide an evolutionary adaptive value account of why genes, for example, taste receptor genes, code for the reward or punisher value of some stimuli. Genes do this

in their own selfish interests, and making a particular taste such as sweet rewarding is very adaptive, for this is much simpler and more flexible than a gene that tries to specify a response such as climbing a tree, picking an apple, and placing it in the mouth. By specifying rewards and punishers, the genes that provide a foundation for emotion are thus acting in their own selfish interests (Rolls, 2014). Tastes are thus important in many emotional and related states, such as the pleasantness of the taste of sweet.

Some olfactory stimuli are primary reinforcers, including pheromones, and some odors such as perhaps the smell of ripe fruit, and the smell of rotting food. An interesting example is that the odors of some individuals may be pleasant because of major histocompatibility complex genes, which specify olfactory receptors that signal reward produced be the smell of another individual with different immune system. The adaptive value is that offspring produced with an individual with a different immune system may have more diverse immune systems, and thereby greater resistance to disease. However, many odors only become reinforcers by a learned, stimulus–reinforcer association. An example is that the odor of the cheese brie may be initially unpleasant, but may become pleasant after learned association with its taste and fatty texture. (Fatty texture may be a primary reinforcer because it is an indicator of a high-energy value food.)

These concepts help to show how taste and smell are closely linked to reward value and emotion. A broad perspective on emotion and the pleasantness of sensory stimuli including taste and smell is provided in *Emotion and Decision-Making Explained* (Rolls, 2014).

We now turn to consider how taste and smell, and their functions related to reward value and subjective pleasantness, are implemented in the brain, again an area in which rapid progress is being made.

Taste Processing in the Brain

Pathways

A diagram of the taste and related olfactory, somatosensory, and visual pathways in primates is shown in **Figure 1**, as the focus of this article is on processing relevant to humans. (The pathways involved in taste in rodents are quite different, with subcortical connections to a pontine taste area, with no granular orbitofrontal cortex so that other areas are more involved in the processing, and with hunger modulating taste processing even in the brain stem (Rolls, 2014).) The multimodal convergence that enables single neurons to respond to different combinations of taste, olfactory, texture, temperature, and visual inputs to represent different flavors produced often by new combinations of sensory input is a theme of recent research that will be described, as is the separation in primates including humans of processing of what the taste is (in the primary taste cortex) from its reward value and pleasantness (in the orbitofrontal cortex and anterior cingulate cortex).

The Primary Taste Cortex

Rolls and colleagues have shown that the primary taste cortex in the primate anterior insula and adjoining frontal operculum contains not only taste neurons tuned to sweet, salt, bitter, sour, and umami as exemplified by monosodium glutamate, but also other neurons that encode oral somatosensory stimuli including viscosity, fat texture, temperature, and capsaicin. Some neurons in the primary taste cortex respond to particular combinations of taste and oral texture stimuli, but do not respond to olfactory stimuli or visual stimuli such as the sight of food. Neurons in the primary taste cortex do not represent the reward value of taste, that is the appetite for a food, in that their firing is not decreased to zero by feeding the taste to satiety (Rolls, 2012, 2014).

The Secondary Taste Cortex

A secondary cortical taste area in primates was discovered by Rolls et al. (1990) in the orbitofrontal cortex, extending several mm in front of the primary taste cortex. Different neurons in this region respond not only to each of the four classical prototypical tastes sweet, salt, bitter, and sour, but also to umami tastants such as glutamate (which is present in many natural foods such as tomatoes, mushrooms, milk) and inosine monophosphate (which is present in meat and some fish such as tuna). This evidence, taken together with the identification of glutamate taste receptors (Zhao et al., 2003; Maruyama et al., 2006), leads to the view that there are five prototypical types of taste information channels, with umami contributing, often in combination with corresponding olfactory inputs, to the flavor of protein. In addition, some neurons respond to water and others to somatosensory stimuli including astringency as exemplified by tannic acid, and capsaicin (Rolls, 2012, 2014).

The Pleasantness of the Taste of Food, Sensory-Specific Satiety, and the Effects of Variety on Food Intake

The modulation of the reward value of a sensory stimulus such as the taste of food by motivational state, for example, hunger is one important way in which motivational behavior is controlled. The subjective correlate of this modulation is that food tastes pleasant when hungry, and tastes hedonically neutral when it has been eaten to satiety. Following Edmund Rolls' discovery of sensory-specific satiety revealed by the selective reduction in the responses of lateral hypothalamic neurons to a food eaten to satiety (Rolls, 1981; Rolls et al., 1986), it has been shown that this is implemented in a region that projects to the hypothalamus, the orbitofrontal (secondary taste) cortex, for the taste, odor, and sight of food (Rolls et al., 1989; Critchley and Rolls, 1996).

This evidence shows that the reduced acceptance of food that occurs when food is eaten to satiety, the reduction in the pleasantness of its taste and flavor, and the effects of variety to increase food intake, are produced in the orbitofrontal cortex, but not at earlier stages of processing where the responses reflect factors such as the intensity of the taste, which is little affected by satiety (Rolls and Grabenhorst, 2008; Rolls, 2012, 2014). In addition to providing an implementation of sensory-specific satiety (probably by habituation of the synaptic afferents to orbitofrontal

Figure 1 Schematic diagram showing some of the gustatory, olfactory, visual, and somatosensory pathways to the orbitofrontal cortex, and some of the outputs of the orbitofrontal cortex, in primates. The secondary taste cortex and the secondary olfactory cortex are within the orbitofrontal cortex. V1 – primary visual cortex. V4 – visual cortical area V4. PreGen Cing – pregenual cingulate cortex. 'Gate' refers to the finding that inputs such as the taste, smell, and sight of food in some brain regions only produce effects when hunger is present (Rolls, E.T., 2005. Emotion Explained. Oxford University Press, Oxford.). The column of brain regions including and below the inferior temporal visual cortex represents brain regions in which what stimulus is present is made explicit in the neuronal representation, but not its reward or affective value, which are represented in the next tier of brain regions, the orbitofrontal cortex and amygdala, and in the anterior cingulate cortex. In areas beyond these such as medial prefrontal cortex area 10, choices or decisions about reward value are taken, with the mechanisms described elsewhere (Rolls, E.T., 2008. Memory, Attention, and Decision-making: A Unifying Computational Neuroscience Approach. Oxford University Press, Oxford; Rolls, E.T., Deco, G., 2010. The Noisy Brain: Stochastic Dynamics as a Principle of Brain Function. Oxford University Press, Oxford; Rolls, E.T., 2014. Emotion and Decision-making Explained. Oxford University Press, Oxford.). Medial PFC area 10 – medial prefrontal cortex area 10; VPMpc – ventralposteromedial thalamic nucleus (tasolfpaths6i.eps).

neurons with a time course of the order of the length of a course of a meal), it is likely that visceral and other satiety-related signals reach the orbitofrontal cortex (as indicated in **Figure 1**) (from the nucleus of the solitary tract, via thalamic and possibly hypothalamic nuclei) and there modulate the representation of food, resulting in an output that reflects the reward (or appetitive) value of each food.

The Representation of Flavor: Convergence of Olfactory, Taste, and Visual Inputs in the Orbitofrontal Cortex

Taste and olfactory pathways are brought together in the orbitofrontal cortex where flavor is formed by learned associations at the neuronal level between these inputs (see **Figure 1**). Visual inputs also become associated by learning in the orbitofrontal cortex with the taste of food to represent the sight of food and contribute to flavor. The visual and olfactory as well as the taste inputs represent the reward value of the food, as shown by sensory-specific satiety effects (Rolls, 2012, 2014).

The Texture of Food, Including Fat Texture

Some orbitofrontal cortex neurons have oral texture-related responses that encode parametrically the viscosity of food in the mouth (shown using a methyl cellulose series in the range 1–10 000 cP), others independently encode the particulate quality of food in the mouth, produced quantitatively, for example, by adding 20–100 μm microspheres to methyl cellulose (Rolls et al., 2003a), and others encode the oral texture of fat. Somatosensory signals that transmit information about capsaicin (chili) and astringency are also reflected in neuronal activity in these cortical areas.

Imaging Studies in Humans

Taste

In humans, it has been shown in neuroimaging studies using functional magnetic resonance imaging (fMRI) that taste activates an area of the anterior insula/frontal operculum, which is probably the primary taste cortex, and part of the orbitofrontal cortex, which is probably the secondary taste cortex. The primary taste cortex in the anterior insula of humans represents the identity and intensity of taste in that activations there correlate with the subjective intensity of the taste, and the orbitofrontal and anterior cingulate cortex represents the reward value of taste, in that activations there correlate with the subjective pleasantness of taste (Grabenhorst and Rolls, 2008; Grabenhorst et al., 2008).

We also found activation of the human amygdala by the taste of glucose. Indeed, the human amygdala is as much activated by the affectively pleasant taste of glucose as by the affectively negative taste of NaCl, and thus provided evidence that the human amygdala is not especially involved in processing aversive as compared to rewarding stimuli.

Odor

In humans, in addition to activation of the pyriform (olfactory) cortex, there is strong and consistent activation of the orbitofrontal cortex by olfactory stimuli, and this region appears to represent the pleasantness of odor. Further, pleasant odors tend to activate the medial, and unpleasant odors the more lateral, orbitofrontal cortex (Rolls et al., 2003b), adding to the evidence that it is a principle that there is a hedonic map in the orbitofrontal cortex, and also in the anterior cingulate cortex, which receives inputs from the orbitofrontal cortex (Rolls and Grabenhorst, 2008; Grabenhorst and Rolls, 2011). The primary olfactory (pyriform) cortex represents the identity and intensity of odor in that activations there correlate with the subjective intensity of the odor, and the orbitofrontal and anterior cingulate cortex represents the reward value of odor, in that activations there correlate with the subjective pleasantness of odor (Grabenhorst et al., 2007; Rolls and Grabenhorst, 2008; Grabenhorst and Rolls, 2011).

Olfactory-Taste Convergence to Represent Flavor, and the Influence of Satiety

Supradditive effects indicating convergence and interactions were found for taste (sucrose) and odor (strawberry) in the orbitofrontal and anterior cingulate cortex, and activations in these regions were correlated with the pleasantness ratings given by the participants (de Araujo et al., 2003). These results provide evidence on the neural substrate for the convergence of taste and olfactory stimuli to produce flavor in humans, and where the pleasantness of flavor is represented in the human brain.

McCabe and Rolls (2007) have shown that the convergence of taste and olfactory information appears to be important for the delicious flavor of umami. They showed that when glutamate is given in combination with a consonant, savory, odor (vegetable), the resulting flavor can be much more pleasant than the glutamate taste or vegetable odor alone, and that this reflected activations in the pregenual cingulate cortex and medial orbitofrontal cortex. The principle is that certain sensory combinations can produce very pleasant food stimuli, which may of course be important in driving food intake; and that these combinations are formed in the brain far beyond the taste or olfactory receptors (Rolls, 2009).

To assess how satiety influences the brain activations to a whole food, which produces taste, olfactory, and texture stimulation, we measured brain activation by whole foods before and after the food is eaten to satiety. The foods eaten to satiety were either chocolate milk, or tomato juice. A decrease in activation by the food eaten to satiety relative to the other food was found in the orbitofrontal cortex (Kringelbach et al., 2003) but not in the primary taste cortex. This study provided evidence that the pleasantness of the flavor of food and sensory-specific satiety, are represented in the orbitofrontal cortex.

Cognitive and Selective Attentional Effects on Representations of Smell, Taste, and Flavor

To what extent does cognition influence the hedonics of food-related stimuli, and How far down into the sensory system does the cognitive influence reach? To address this, we performed a fMRI investigation in which the delivery of a standard test odor (isovaleric acid combined with cheddar cheese odor, presented orthonasally using an olfactometer) was paired with a descriptor word on a screen, which on different trials was 'Cheddar cheese' or 'Body odor.' Participants rated the affective value of the test odor as significantly more pleasant when labeled 'Cheddar cheese' than when labeled 'Body odor,' and these effects reflected activations in the medial orbitofrontal cortex/rostral anterior cingulate cortex that had correlations with the pleasantness

ratings (de Araujo et al., 2005). The implication is that cognitive factors can have profound effects on our responses to the hedonic and sensory properties of food, in that these effects are manifest quite far down into sensory processing, so that hedonic representations of odors are affected (de Araujo et al., 2005). Similar cognitive effects and mechanisms have now been found for the taste and flavor of food, where the cognitive word-level descriptor was, for example, 'rich delicious flavor' and activations to flavor were increased in the orbitofrontal cortex and regions to which it projects including the pregenual cingulate cortex and ventral striatum, but were not influenced in the insular primary taste cortex where activations reflected the intensity (concentration) of the stimuli (Grabenhorst et al., 2008).

In addition, we have found that with taste, flavor, and olfactory food-related stimuli, selective attention to pleasantness modulates representations in the orbitofrontal cortex, whereas selective attention to intensity modulates activations in areas such as the primary taste cortex (Grabenhorst and Rolls, 2008; Rolls et al., 2008). Thus, depending on the context in which tastes and odors are presented and whether affect is relevant, the brain responds to taste and odor differently. These findings show that when attention is paid to affective value, the brain systems engaged to represent the stimulus are different from those engaged when attention is directed to the physical properties of a stimulus such as its intensity. This differential biasing by prefrontal cortex attentional mechanisms (Grabenhorst and Rolls, 2010; Ge et al., 2012) of brain regions engaged in processing a sensory stimulus depending on whether the cognitive demand is for affect-related versus more sensory-related processing may be an important aspect of cognition and attention, which have implications for how strongly the reward system is driven by food, and thus for eating and the control of appetite (Grabenhorst and Rolls, 2008, 2011; Rolls et al., 2008).

There are individual differences in the representation of the reward value of food, for example of chocolate, in the orbitofrontal cortex (Rolls and McCabe, 2007). Overeating and obesity may be related in many cases to an increased reward value of the sensory inputs produced by foods, and their modulation by cognition and attention, that override existing satiety signals. The findings described here thus have implications for understanding what causes obesity (Rolls, 2012, 2014).

Tattoos and Body Modification

Mary Kosut, State University of New York, Purchase, NY, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

This article examines tattooing as an ancient and contemporary form of body inscription and modification. It frames the popularity of tattooing in the Western World, in relation to other modern body modifications and within the landscape of consumer culture. Showing parallels between the motivations and meanings of contemporary tattoo practices, a historical overview of tattoos in premodern and non-Western cultures is presented. The divergent ways in which scholars have approached tattooing is examined, juxtaposing research in the behavioral sciences that links tattoos to deviant and antisocial behaviors with ethnographic and social–scientific studies that place tattoos within cultural, symbolic, esthetic, and prosocial frameworks.

Introduction

All humans undergo physical transformation as part of becoming and being with other bodies in the material and social world. The body is the intersection between self and society; it is a medium through which we negotiate life; and a conveyer of personal and social meanings. As a simultaneously biological and cultural entity, our body immediately succumbs to a process of modification at birth, ending when fleshy mortification finally betrays us. Throughout the life course, our bodies grow (for example, in height, muscle mass, and physical and mental dexterity) and they inevitably decline, suffering injuries, unforeseen breakdowns, and malfunctions. The human body is a vehicle of boundless pleasure and unthinkable pain and abjection. While bodily processes and experiences such as aging, illness, and dying are universal, our understanding of these processes and experiences depends upon the individual and the cultural contexts in which we live. Increasingly, in the neoliberal West we are seen as being responsible for what happens to our own bodies, especially with regard to health and beautification (which could be described as the visual evidence of well-being). To some degree, all of us are expected to engage in body inscription and modification, regardless of access to resources and levels of opportunities – particularly in affluent and technologically modernized countries.

Cross-culturally and throughout prehistory and history, people have participated in transitory or permanent corporal modification for sundry reasons. How humans modify their bodies – the where, what, and when – marks people as individuals and identifies individuals with large groups. While there are many public and immediately visible transitory markers that convey the body/self to others – hairstyle, clothing, and jewelry – humans are also drawn to permanent body modifications. Social science research reveals a range of ancient body modification customs, including earlobe and penis elongation, foot binding, head molding, neck stretching, branding, and scarification.

However, tattooing is arguably the oldest and most widely used form of permanent body modification. From a historical and anthropological perspective, it can be argued that where there is skin and opportunity, you will find tattooed bodies. Many social scientists are exploring the question of why tattoos have become so popular in the West in the late twentieth and early twenty-first centuries. While there are many answers – tatooos have become more socially acceptable, they are a means to visualize individuality, a way to display political or social affiliations – the most comprehensive answer is straightforward: tattoos are effective. Tattoos are tremendously functional on both micro- and macro-social levels.

Within different cultural contexts, tattoos may be viewed and experienced positively, but there are others who will likely always think of tattoos pejoratively, not as self-modification but as self-mutilation. This terminology is highly significant as the former term (modification) indicates that a person is engaged in body/self work that is reasonable to some extent; while the latter is a behavior that is linked to mental or physical illness and suffering. Modern tattooing is contradictory, currently visible, and popular in mainstream media platforms; however at the same time, it is considered unacceptable, if not categorically harmful. In contemporary Western cultures, tattoos have numerous meanings and are situated within an extensive range of social contexts. Individual motivations for getting a tattoo are extraordinarily varied; and social class, gender, race, sexuality, occupation, age, and geographic location may influence tattoo choices and experiences.

Current cross-cultural tattoo practices affirm the fluidity and malleability of the body in contemporary consumer culture, where it is taken for granted that those with a degree of economic capital will likely engage in some sort of work on the body/self in the name of maintenance, improvement, health, beauty, and the pursuit of youthfulness (see Shilling, 1993; Sweetman, 1999). The increase in the popularity of tattoos coincides with the increasing popularity of other forms of body modification. Ultimately, modern, privileged bodies are understood as a site of potential transformation and adjustment, whether through dietary regimes and beautification rituals or as more nonnormative and potentially stigmatizing visible large-format tattoos. In some cases, people engage in both acceptable (breast implants), and socially objectionable modifications (septum piercing). The body is not a static object that we are given, but rather, a flexible and changeable medium that we can rework and potentially recreate into a more attractive or functional form.

 http://dx.doi.org/10.1016/B978-0-08-097086-8.64027-8

Although tattooing is a permanent and decorative form of body modification with a lengthy history, it should be framed within a contemporary landscape of larger technologies and consumer practices including a sharp increase in semi-permanent and permanent cosmetic procedures like botox injections, laser-hair removal, breast implants, liposuction, and other invasive and potentially risky surgeries. However, tattoos should not be lumped with trendy transitory and sartorial forms of expressions. Because the act of getting tattooed typically encompasses three distinct stages of varying length (preplanning, receiving the tattoo, and an after-care regime and healing process) it cannot be compared to the purchase of a pair of sneakers or having your hair dyed blue, no matter how reflective and discriminating the consumer may be. This is because a tattoo is a consumer product whose consumption cannot be divorced from its mode of production. The idiosyncratic act of tattooing, permanently reinscribes the living body – a thinking, breathing, sweating, and wrinkling entity – with a type of symbolic agency that is ongoing and embodied.

Prehistoric and Non-Western Tattoo Practices in the Historical Context

The recent history of tattooing is directly influenced by globalization and the advent of new media technologies – tattoo blogs, websites, and online galleries are now ubiquitous across the Internet. Idiosyncratic tattoo traditions, philosophies, and styles are virtually shared and displayed, fertilizing new hybrid tattoos born from a culture of appropriation. However, ancient tattoo practices demonstrate that cultural forms have always migrated across continents and societies, albeit at a much slower pace. Tattoos clearly played a significant role within many premodern, non-Western societies. Anthropological studies document a wide range of practices chronicling the symbolic significance of tattoos and their functions. Significantly, the meanings and uses of ancient tattoo practices share many commonalities with contemporary tattoo customs. Modern-day tattoo narratives suggest that there are certain traditions, for example, using the tattoo to commemorate a rite of passage or a major accomplishment or to memorialize the death of a significant other, that transcends historical and cultural boundaries.

The earliest tattooed bodies date to roughly 6000 BCE – the oldest and arguably most well-known (and well-studied) is the mummified 'Iceman', discovered in the Ötztal Alps on the Italy–Austria border in 1991, dated 5300 BCE. The mummified body is covered in 57 tattoos including lines scored in groups on his lower back and ankles, a cross behind his right knee and two rings circling his left wrist. Anthropologist Lars Krutak speculates that the tattoos may have been connected to the Iceman's medical condition as 80% of the tattoos on his body overlap with Chinese acupuncture points. Krutak (1999) makes a strong case for the medicinal usage of tattoos by the indigenous Yupik peoples of St. Lawrence Island in Western Alaska. This research expands our search toward understanding the possible reasons why people tattooed themselves in early human history, and how tattoos may have functioned in relationship to health and embodiment. In addition to having spiritual and symbolic purposes, tattoos may have served in easing pain, promoting health, and curing illness. This connection between tattoos and curative medicinal procedures offers an approach that is at odds with studies that posit tattoos as a sign of pathology or deviant behavior (see Parry, 1933; Lombroso, 2006; Favazza, 1996; Stirn and Hinz, 2008; among others).

Archeologists and anthropologists have also found evidence of tattooing among the indigenous peoples of North and South America, Africa, and throughout the Pacific region. In fact, the oldest material evidence of tattoo in the world is from a mummy dated to 6000 BCE from the Chinchorro culture of South America. However, there has been much research centered on the prevalence of tattoos in Ancient Egypt, possibly due to the significant number of well-preserved material artifacts. There have been numerous tattooed female mummies dating backing to 2000 BCE, as well as female figurines and tomb scenes with tattooed bodies. Archeologist Joann Fletcher theorizes that although it has long been assumed that tattoos were the mark of prostitutes or were meant to protect women against sexually transmitted diseases, the tattooing of ancient Egyptian women "had a therapeutic role and functioned as a permanent form of amulet during the very difficult time of pregnancy and birth"(http://www.smithsonianmag.com/history-archaeology/tattoo.html, accessed 20.12.13). This linkage between tattoos, fertility, and reproductive processes is comparable to tattoos as a form of acupuncture, as the tattoos either literally or symbolically helped their bearers to come to terms with illness and the tremendous physical vulnerabilities that characterized premodern embodiment.

While the specific meanings of tattoo in preindustrialized cultures are based upon academic speculation, it is apparent that the tattoo was an integral aspect of collective social life for some cultures. From the perspective of sociologist Emile Durkheim (1995), tattooing is emblematic of collective consciousness – a tangible mark of society upon the individual body. For example, in his study of Polynesian tattooing, anthropologist Alfred Gell (1993) asserts that tattooing played an integral part in the organization and functioning of major institutions (politics, warfare, religion, and so on), and that tattoos were visual documents of the social systems in which tattooed people were embedded. In addition to larger macro-social functions, tattoos were believed to be a sign of beauty and individuality in Poylnesian cultures (Gell, 1993). They were also employed to mark rites of passage to adulthood, indicate political status, and commemorate major events like funerals and weddings (Kuwahara, 2005).

The Maori of New Zealand produced particularly sophisticated and elaborate designs referred to as 'Moko', which are differentiated from other Polynesian tattooing forms because of its symbolic significance, stylistic elements, and excruciatingly painful method of application by use of hand tools (Rubin, 1988; Sanders, 1989; Freidlander and King, 1999). The act of receiving a tattoo by this method required an ability to endure extend hours of physical discomfort. Enduring pain and pushing the body's physical threshold is a key element and a common practice in highly meaningful cultural and spiritual rituals. Some researchers have suggested that the purpose of Moko was to indicate status or rank (Brain, 1979; Sanders, 1989); while others have proposed that the meanings of Moko may incorporate existential characteristics, proposing

that it may have allowed individuals to achieve 'completeness' because it linked them to their ancestors and enabled an 'ideal social personality' (Gathercole, 1988).

Like other societies on the Pacific Rim, Japan has a long and rich tradition of tattooing (McCallum, 1988; Schildkrout, 2004). Artifacts such as stone tools and clay figurines suggest that tattooing may have been present as early as the Jomon period (10 000–300 BCE). While very early accounts of Japanese tattoo are highly speculative, texts from the Kofun period (CE 300–600) indicate that people of higher status had tattoos, as did criminals and thieves. Modern Japanese literary texts suggest parallels between American and Japanese tattoo cultures. Although extremely divergent in terms of esthetics (iconography and stylization), in both cultures tattoo went through lengthy periods of criminality and marginalization.

In Japanese, tattoo is known as 'irezumi' – 'ire' meaning to insert and 'zumi' referring to the pigments used. Irezumi, which emerged and flourished within the Edo period (AD 1600–1868), is distinguished by imagery that includes koi, dragons, warriors, and other mythical creatures surrounded by stylized aquatic and floral patterns such as waves and chrysanthemums (Kitamura, 2003). Still practised today and revered as an art form by many tattoo historians and aficionados, vividly elaborate irezumi designs often encompass large areas, and in some cases, the entire body. Regardless of its widely acclaimed esthetic qualities, just as tattooing was prohibited and condemned by government authorities in the United States during most of the twentieth century, during the Edo period the Tokugawa Bakufu (military government) prohibited tattooing. In both cultures the tattoo went underground, migrating to the bodies of the urban working classes. Despite its peripheral social location, it did not disappear completely in either case. Just as the tattoo was a macho emblem for some working-class men and women in the United States, irezumi was quite popular among firefighters and tradesmen who were known for their rowdy behavior.

By the nineteenth and twentieth centuries in Japan, tattoos were deemed immoral and a sign of barbarism and some Japanese criminals were punished by having their faces tattooed (Sanders, 1989; DeMello, 2000). Tattoos became commonly associated with people working in the underground economy who were involved in prostitution, extortion, and petty crime. Likewise, tattoos have a similar history in Russian prisons and within organized crime syndicates. Strictly forbidden legally and normatively, mainly gamblers and members of the Yakuza (Japanese organized crime syndicate) had tattoos until the end of World War II, at which time laws prohibiting tattooing were overturned. Interestingly, Western interest in tattooing revived the practice in Japan and the United States in the decades that followed. Many American and European tattoo artists continue to be greatly influenced by irezumi masters, and Japanese-inspired imagery remains popular among contemporary tattoo aficionados.

Nevertheless, some research assigns colonialism and the seafaring culture as giving rise to the birth of the modern Western tattoo (Sanders, 1989; DeMello, 2000). In the late 1700s, Captain James Cook encountered tattooing while exploring the islands of the South Pacific. He introduced the then exotic practice to European society, reinvesting tattooing with new meanings in the West. Cook was responsible for bringing the Tahitian word 'ta-tu' or 'tatau' (to strike or mark) into common parlance. In Europe and the United States, for most of the eighteenth and nineteenth centuries, tattooing was associated with marginalized populations; side show and circus workers, criminals, sailors, gang members, and the economically underprivileged. Nonetheless, there is evidence to suggest a short-lived tattoo fad within the circles of the cultural elite in Europe and the United States during the 1880s, because some members of polite society got tattoos as symbols of exoticism and distinction. The popularity of the tattoo among the 'leisured class' waned within a decade due to the invention of the electric tattoo machine. At this stage, tattoo became more affordable and accessible to the working- and middle-classes. However, members of the working class and the military continued to get tattooed before, during, and after this period.

It was not until the mid-1960s that a noticeable shift in tattoo culture, commonly referred to as the 'tattoo renaissance', revived the practice and signaled major changes in esthetics, population, and discourse (Rubin, 1988; Sanders, 1989; DeMello, 2000). Major social changes, including the civil rights and women's movements, resulted in shifts in American culture that produced fertile ground for a resurgence of subcultural, anarchistic, and artistic activities. The 1960s counterculture (the feminist, social justice, and antiwar movements) led to a renewed interest in tattoos within a climate of protest and a focus on the body as a site of symbolic dissention. Recognizable symbols such as peace signs, butterflies, marijuana leaves, and so on were used to distinguish rebellious bodies.

Tattoos as Deviant Behavior in Western Society

Western tattooing has always been a signifier of 'outsiderness', often overshadowed by symbolic associations with marginalized groups and subcultures. Most journalistic accounts of contemporary tattoo cultures begin with a familiar hook: tattoos were for 'them' (the disenfranchized, marginalized, incarcerated, impoverished, macho, crude, criminal) but now they are for 'us' (privileged, educated, mainstream, sophisticated, law abiding). Even though tattoos have been cleaned up – symbolically, esthetically, and culturally – and hold more positive cultural capital today than at any point in modern history, they are still tethered to forms of social marginality. Prisoners, gang members, and those with ties to illegal alternate economies are a part of tattoo's early history in the United States. Regardless of how tattoos may be commodified or esthetically elevated, they will never be sterilized and whitewashed to the point of being drained of all of their oppositional power. Even now tattoos semiotically provoke and disturb mainstream norms of body propriety and acceptability.

In the behavioral sciences especially, there is a history of equating the presence of tattoos to psychological disorders and socially deviant behavior (Copes and Forsyth, 1993; Grumet, 1983; Loimer and Werner, 1992). The literature is dominated with studies centering on patients in clinics and those in prison (Newman, 1982; Gittelson et al., 1969; Hamburger, 1966). This highly select group of individuals is typically described as being more likely to exhibit personality disorders than those found within the general population. As many tattoo scholars

have pointed out, the conclusions of reports such as these rely on populations found within these specialized institutions. The tattooed individuals under investigation were already diagnosed and labeled as psychopathological, or were convicted of committing a criminal act. Thus, the association made between tattoos and criminality has been at times spurious.

In the 1960s, studies purported that the presence of tattoos was indicative of homosexual inclinations and suppression of sexual desires (see Post, 1968; Yamamoto et al., 1963). In these cases, one innately and historically deviant outsider (the homosexual) was linked with another (the tattooed). The relationship between tattooing and forms of perceived sexual deviancy continue to attract behavioral scientists. An association between tattoos and certain sexual behaviors has recently received attention, as contemporary researchers have reported that tattoos may be connected with heightened sexually activity, becoming sexually active at a younger age, and having sex outside of committed relationships (Koch et al., 2005; Carroll et al., 2002). This type of framing works well with a more conservative political agenda, especially those advocating for family values and a desire to return to a traditional definition of heterosexual, monogamous marriage as the ideal. The individual body is always subjected to a matrix of powerful social and political discourses.

The motivations for getting a tattoo are also characterized as negative by certain researchers. Studies maintain that people may get tattoos because of antisocial tendencies and psychiatric disorders. For example, it has been suggested that the desire to tattoo oneself may be the result of extraversion, indicated by the presence of low levels of cortical arousal and a need for constant stimulation. Armando Favazza, a cultural psychiatrist, asserts that a psychiatric diagnosis cannot be presumed in persons who engage in tattooing (and also piercing and branding), although as a group, such persons 'probably' (emphasis added) have increased levels of pathology (1996). This diagnosis as it were, may be speculative but nonetheless aids in advancing the idea that there may be something inherently pathological about tattoos.

Within the field of psychology, some studies have focused on behavioral and individual differences between tattooed and nontattooed people (Tate and Shelton, 2008). A related body of research suggests that tattooed students are psychologically more inclined toward behavior that is impulsive, riskier, or sensation-seeking; including the use of illegal drugs and binge-drinking. Where notable differences have been found, the findings are often statistically insignificant and the extent to which such differences have real-world implications has been questioned. The inability to generalize findings may be related to sampling issues.

With few exceptions, in most quantitative studies in which differences between tattooed and nontattooed individuals have been examined, the population has been college students. Given the age cohort, and taking into account the cultural norms of college as a distinctive period of time before adulthood and its responsibilities, it is not surprising that these sample populations would report higher levels of perceived risky and reckless behavior. Sexual exploration, drug use, and alcohol consumption on college campuses is not automatically regarded as anomalous behavior within this institutional context.

Early criminologist, Cesare Lombroso (1836–1909), championed the concept of degeneracy as the central explanation of deviancy and linked tattooing to criminal behavior (1876). According to Lombroso, criminals were innately primitive and atavistic beings with recognizable physical deformities. Tattoo was a physical manifestation of a biologically criminal person – an easily discernable sign of pathology. Throughout much of the twentieth century, clinical psychiatrists and psychologists associated tattoo with mental illness, criminal behavior, self-mutilative behaviors, and sexual deviancy. The presence of tattoos was (and still is) being studied in relation to psychological abnormalities and unhealthful mental states. The image of a tattooed patient confirms that internal illness can manifest itself externally. In this case, the body of the other is constructed from inside and out.

Current Trends in Tattoos and Tattoo Research

In the United States, people tend to be divided as to whether tattoos are inherent mistakes, obdurate esthetic and social blemishes, or semiotic celebrations of self, embodiment, and connections to significant others. For example, a 2013 article about the visibility of tattoos in the academia in the *Chronicle of Higher Education* entitled 'The Inked Academic Body' discusses how American professors increasingly have visible ink (http://chronicle.com/blogs/conversation/2012/10/25/the-inked-academic-body/, accessed 10.01.14). The author, himself a tattooed professor, writes from a tattoo positive standpoint describing his own as a way to control his body and agentically modify it in a way that is nonnormative, but highly functional nonetheless. Tattoos may be read as a positive sign by some students; a kind of social can-opener that may mitigate the power imbalance between student and professor. While seemingly benign in its writing style and assertions, the article sparked a very contentious discussion thread. The online comments drew a sharp line between those who accept or appreciate tattoos as agentic self/body work, and those staunchly opposed to tattoos. One person stated that their heavily tattooed arm (or sleeve) had 'deep meaning'; however, another poster described tattoos as a 'tawdry act of self display'. This polarizing discussion illustrates the sharp divisions and the symbolic power tattoos can generate – prejudices and emotions often flare when tattoos become public.

Regardless of how they are framed, tattoos are today more popular in the United States than at any other time in history. Most polls indicate that roughly one in five American adults between the ages of 21–50 have tattoos, and that this statistic has continued to rise. According to a 2012 Harris Poll, adults aged 30–39 years are most likely to have a tattoo (38%) compared to both those younger (30% of those aged 25–29 years and 22% of those aged 18–24 years) and older (27% of those aged 40–49 years; 11% of those aged 50–64 years; and just 5% of those aged 65 years and older). Women are slightly more likely than men (23 vs 19%) to have one (one in five U.S. adults now has a tattoo. http://www.harrisinteractive.com/NewsRoom/HarrisPolls/tabid/447/mid/1508/articleId/970/ctl/ReadCustom%20Default/Default.aspx, accessed 08.01.14). Interestingly, most of the people polled (84%) said that they did not experience tattoo regret. The popularity of tattoos is certainly not

limited to the United States, as studies show that in England there is also an attraction to tattooing, again with one in five people reporting having inked bodies (do you have a tattoo too? Why Britons love being inked. http://metro.co.uk/2013/02/21/do-you-have-a-tattoo-too-why-britons-love-being-inked-3504642/, accessed 12.01.14).

Tattooing is a multifaceted, embodied phenomenon, not only in the concrete sense of literally inscribing layers of skin with outwardly visible pigment on areas of the body, but also in cultural, symbolic, and socio-psychological terms. Ethnographic and qualitative studies of modern tattooing explore the range of meanings that tattoos hold for those who have them; and how wider cultural understandings of tattoos have shifted in the context of radical global and technological shifts (see Schildkrout, 2004).

This research, conducted mainly by sociologists, anthropologists, and cultural studies scholars, focuses on populations in the postindustrial West, particularly in North American and Europe. Unlike psychological studies that have a tendency to conceptualize tattoos within frameworks of deviant behavior, risk-taking, and antisocial tendencies, qualitative research more often examines how tattoos relate to social scientific variables such as gender, social class, sexuality, and sense of self-identity. For example, Atkinson (2002a) offers a comprehensive treatment of contemporary tattooing practices. As a sociologist, ethnographer, and heavily tattooed person, he situates tattoo within a sophisticated micro- and macro-social frameworks, deliberately avoiding the rhetoric of deviance.

Ethnographic research from a phenomenologically driven frame explores how tattoos hold a multiplicity of meanings, and are related to self-construction and embodied knowledge. As many scholars have shown, tattoos are extensions of the self and serve as a means to visually communicate via the body (DeMello, 2000; Irwin, 2003; Kosut, 2000; Pitts, 2003; Sanders, 1989). The communication may be internal (as a form of self-reflexive body work) or external in the case of visible tattoos, or both. Visible tattoos do invite sociality, which can elicit both negative and positive responses.

The same image on the same body, however, may be read differently depending upon social environment. For example, tattoos on the bodies of gang members and prisoners that affiliate them with antimainstream and illegal activities can be interpreted simultaneously as beautiful and artistic, and also totally at odds with what is esthetically acceptable in larger society. As anthropologist Susan Phillips' (2013) ethnographic study of Chicano ex-gang members illustrates, the corporeal and material strategy of using a tattoo to survive in one social context can lead to stigmatization, exclusion, and discrimination in others. Tattoos may be creative expressions of the self at the intersection of art and embodiment, but the same tattoo can be read as both abomination and art.

Until recently, tattoo research tended to focus mainly on the perspectives of tattooed men. As tattooing has increased in popularity, and more women are getting tattooed, researchers are paying attention to the unique, embodied experiences of women with tattoos. Within the context of a patriarchy, the female body (or those identified visually as such) are subject to visual surveillance, commentary, harassment, and forms of public and private social control. Given embodied gender politics it is not surprising that women have gotten tattooed as a way to claim ownership of the body and as a form of personal empowerment.

Getting a tattoo is a visceral and direct way to both enact and announce a degree of agency and embodied authority to others. According to Mifflin (1997), the sexual revolution of the 1960s assisted the resurrection of tattoos from disrepute and situated them within feminist and counter-cultural movements. In the last decade, some women have also used tattooing as a way to reclaim the body after sexual abuse or trauma (see Atkinson, 2002a; Braunberger, 2000; DeMello, 2000; Pitts, 2003). In these examples, tattooing is experienced and conceptualized as a form of epidermal self help, rather than self-injury.

Scholars explore how some tattooed people process and interpret their changed identities and bodies after permanently modifying them. Sociologist D. Angus Vail, an ethnographer and tattoo enthusiast proposes that tattoo collectors (people who conceive of their bodies as canvases to be filled with tattoo artwork), begin to see their ink as art through a process of social interaction with key professionals in tattoo communities (1999). Such approaches contribute to the demystification of tattoos within the academia by establishing their relationship to functioning members of the mainstream; and they also semiotically elevate the tattoo's cultural status by classifying certain tattoos as esthetically significant.

Recently, scholars have called for 'prosocial' conceptualizations of tattooing that explore how tattoos constructively contribute to a sense of self and positive social interactions (see Strohecker, 2011). Ethnographic researchers assert that in many ways tattoos actually can, in essence, be good for us encouraging sociality. This burgeoning body of work demonstrates a paradigmatic shift in academic approaches to tattooing through the explicit rejection of deviance-driven stereotypes that prevailed for well over a century in the United States. Such a shift in interpreting the meaning and purpose of tattoos illustrates how theoretical conceptions of embodiment and the body (as an object of study) are as malleable as the human body itself. In fact, tattoo as a form of body modification is frequently framed under the heading of body art (Sanders, 1989; Kosut, 2013).

Tattoo designs have changed radically in the West since Samuel L. Riley first invented the electric tattoo machine in 1891, allowing for faster and less painful application. This led to the first spike in tattooing as a populist trend and set the stage for the beginning of a revolution in the esthetics of tattooing. While the ability to tattoo well requires skill and precision and a basic understanding of how a tattoo machine or tattoo gun works, framing tattoos as an art fundamentally changed the way that tattooists and clients viewed tattoos. Some professional tattoo artists have themselves inadvertently or purposefully advanced tattoo as an art, rather than a popular body modification or blue-collar craft. Clinton Sanders (1989) was one of the first sociologists to write about how tattooists and tattooed people understood tattoo as art in the 1980s. As such, it is more akin to drawing and painting rather than more craft-based mediums (Sanders, 1989; Kosut, 2013).

The formulation of professional tattoo organizations and the medicalization of tattooing have ushered in standard practices and procedures that have effectively changed the environment and act of getting tattooed. Once known as

tattoo shops, today tattoo studios prevail, some of which feature 'guest artists', long wait lists for appointments, and gallery-like environments where tattoo flash (drawings) and tattoo-inspired art work may be for sale on the walls. Tattoo studios are pleasant, highly estheticized, and professionally run. Just as tattoo shops have shifted into tattoo studios, tattooists are also commonly referred to as tattoo artists. A tattoo artist is expected to do original tattoo design work, be able to tattoo in a proficiency of styles, and possess a very high level of skill. Some tattoo artists have attended art school and earned fine arts degrees in classical mediums like drawing and painting. Even those who are not academically trained are often at least familiar with esthetic and art-historical discourse and frame and/or compare tattooing to styles of painting and couch them within esthetic-cultural theories (Kosut, 2013). The emergence of tattoo studios and a new generation of international tattoo artists has helped pave the way for the acceptance of the tattoo as body art – a quasi-legitimate esthetic practice that hovers between the landscapes of high, low, and popular culture.

The term body art is now ubiquitous in mass-mediated and academic discourses, and rarely challenged as a categorical referent in either milieu. Tattoo scholar Matt Lodder (2014) argues that art historians and social scientists alike have yet to explicitly examine tattoos from an art historical perspective (as body art). He argues that the methodologies and theories employed in critical analyses of other mediums, painting or sculpture, for example, can and should be applied to the genre of tattoo as an art form. This reframing of tattoo art within scholarly literature, positions tattoos on an art-historical scaffold. It gives credence to 'taken for granted' and popular conceptualizations of what body art may consist of (form), the way in which it is created (process), and how it can be identified according to formalist concerns such as line, balance, and perspective (content). This approach to tattooing is quite different from the previous studies mentioned that conceive of tattoo as an extension of the embodied self within social interaction. Here the tattoo and the tattooed body are framed as objects – media akin to paint and canvas. This approach takes the colloquial phrase of 'viewing skin as canvas' quite seriously and literally.

Abstract

Charles Taylor is one of the world's leading social philosophers. He has made important contributions to debates in contemporary political theory, identity politics, and philosophy of the social sciences. He has also penned important studies of Hegel, the rise of Western modernity as well as Western secularity. In what follows, I briefly describe the various facets of his academic career before explicating the salient features of his work in the philosophy of the social sciences.

Professional Life

Charles Taylor was born in 1931 in Montreal and, with the exception of 2 years in which he attended a boarding school in Ontario, spent most of his childhood there. He then completed his undergraduate studies in History at McGill University. In 1953, Taylor left Montreal to pursue a PhD in Philosophy at Oxford. In 1961, he returned to Montreal and a professorship at the Universite de Montreal before moving on to an appointment at McGill. Except for a 5-year period (1976–81) when he returned to Oxford to hold the Chichele Chair of Political Philosophy, Taylor had been a notable member of McGill's faculty. After becoming an emeritus professor at McGill, Taylor taught for several years at Northwestern University. Besides his academic work, Taylor has been a prolific political actor and political commentator in both Quebec and Canada.

Overview of Taylor's Academic Writings

Taylor has penned some of the most influential pieces in the philosophy of the social sciences, contemporary political theory and Western intellectual history. In the first area, Taylor, along with thinkers such as Alasdair MacIntyre, Hans Georg Gadamer, and Paul Ricouer has been a leading critic of attempts to model the study of man in the social science on natural scientific models. Such models, particularly behaviorist and what calls atomist ones tend to marginalize the role of culture and the self-interpretation of cultural values in human agents self-understandings of their actions. Like Gadamer and Ricouer Taylor's work in this area has become synonymous with a hermeneutical approach to the social sciences, an approach which makes the self-understandings of agents the most conceptually significant element in one's explanation of a given social phenomena. Taylor's work has been highly influential and has drawn a wide array of rejoinders from mainstream social scientists who repeatedly have accused him of underplaying the predictive power of behaviorist and atomist models. These works have also placed him in debate with the German scholar Jurgen Habermas, who early in his career argued that Taylor's hermeneutical model left little room for engaging in critique of the false self-understandings of agents.

As a political theorist, Taylor, drawing of his lifelong involvement of the politics of native Quebec and Canada as well as his magisterial study of Hegel, has composed a number of highly influential essays on liberalism, multiculturalism, the fragmented nature of modern life, and the economic injustices of liberal capitalism. In the 1980s Taylor's work on liberalism was lumped together with that of MacIntyre as part of a supposed communitarian strand of political theory. Taylor (like MacIntyre) was never comfortable with the communitarian label. However, this did not stop his critiques of liberal theory from drawing waves of commentaries from liberal critics of communitarianism. The most trenchant was and still is fellow Canadian Will Kymlicka who argued that contra-Taylor (and MacIntyre) liberals do not rely on a context-free notion of rationality for the justification of their principles but in fact often root them in some appeal to common norms and understandings. Taylor's essay 'Multiculturalism and the Politics of Recognition' was one of the seminal texts in the 1990s through early 2000s identity politics debates transpiring across the humanities and social sciences of Anglo-American academia. The main source of controversy created by the piece had to do with his Hegelian understanding of recognition and its role in human life with defenders and fellow intellectual travelers like Axel Honneth pushing for a greater role for recognition in social theory and critics (particularly in the United States) feeling Taylor's usage of the term was overdone.

Finally, as an intellectual historian, Taylor is well known for not only his aforementioned work on Hegel but also for producing two of the most influential studies of Western modernity, *Sources of the Self* and *A Secular Age*. These texts are generally acknowledged as two of the more persuasive attempts at understanding the various ethical features of Western modernity or what Taylor calls the modern social imaginary, a moral ontology that, Taylor maintains, those living within contemporary Western liberal democracies are always already informed by when they attempt to publicly reason with other members of said societies. This work has been lauded by its defenders for its breadth and ambition and attacked by its critics for being too reductionist in its account of Western identity and too influenced by Taylor's own Catholic spirituality.

The scope and influence of Taylor's professional academic work has recently been recognized beyond academia. In 2007, he was awarded the Templeton prize for Progress Toward Research about Spiritual Realities. In 2008, he was awarded Japan's Kyoto Prize for his lifelong achievements in Philosophy.

Taylor's Social Scientific Thinking Briefly Explained

Taylor's Critique of Analytical Philosophy and Naturalist Approaches to the Social Sciences

Taylor has always been wary of analytical moral and political philosophy because its focus on the right as opposed to the good 'restricted our understanding of what morality is.' These models view "morality as concerned with questions of what we ought to do and to occlude or exclude questions about what it is good to be or what it is good to love. The focus is on obligatory action, which means that it turns away from issues in which obligation is not really the issue, as well as those where not just actions but ways of life or ways of being are what we have to weigh" (Taylor, 2011a: 3). The main culprits here are single term moralities like what one sees in John Rawls' *A Theory of Justice* that focus exclusively on issues of justice-benevolence and thus shorten our moral world by focusing only on what we are obligated to do (Taylor, 2011a: 10). Taylor, by contrast, insists that we also focus on ideals like the dignity of each human life that ethically move us into having a deeper concern with moral issues like the obligations justice entails (Taylor, 2011a: 11).

Taylor's antipathy toward analytical moral and political philosophy is an outgrowth of his longstanding criticisms of social scientific thinking modeled on the natural sciences. Taylor's hermeneutical optics emphasizes the manners in which man acts as a self-interpretative animal. To see man as a self-interpretative animal is to see that the meaning of an entity cannot be understood independently of the subject's interpretation of it. "What is interpreted is itself an interpretation; a self-interpretation which is embedded in a stream of action. It is an interpretation of experiential meaning which contributes to the constitution of the meaning" (Taylor, 1985a: 26).

As self-interpretative animals, we are also creatures whose self-identity is constituted through intersubjective or dialogical actions with others. These acts by which we share a sense of agency with those whom we act and interact with, are vital to our self-understanding of who we are and the world we inhabit since "we cannot understand human life merely in terms of individual subjects, who frame representations about and respond to others, because a great deal of human action happens only insofar as the agent understands and constitutes himself or herself as integrally part of a we" (Taylor, 1991: 314). This means that our identity is never simply defined in terms of our individual properties. It is situated within a social space making us partly define ourselves through our interactions with others.

Naturalist social science models underemphasize the features of man's self-interpretative and dialogical social existence, preferring to model the study of man on the natural sciences. These approaches valorize "the omnicompetence of post-Galilean science, (and) believes that it can cope with life-related values – survival, flourishing as a living being, including health, strength, energy, the desires which de facto accompany life, for sex, food, (in certain cases) dominance …. But it cannot see how values of an incommensurably higher range can have a place in post-Galilean nature" (Taylor, 2000: 245). Moreover, naturalist theories suggest that not only can "man be seen as a part of nature – in one sense or other this would surely be accepted by everyone – but that the nature of which he is a part is to be understood according to the cannons which emerged in the seventeenth-century revolution in natural science"(Taylor, 1985b: 2).

Naturalist social science models are the product of what Taylor in *A Secular Age* refers to as the modern need for 'bifocal' grasps of reality. One is an objectifying account of human nature and reality while the other is a creative act through which humans attempt (to use Arendtian language) to create durable worlds fit for living (Taylor, 2007: 182). This underlies a battle between objectivating social scientists and economists and their antipositivist critics like Taylor who chafe at the effects on freedom and authenticity that the former's work sanctions. Taylor's sympathies for the latter camp stem from the point that our selfhood, "cannot be treated scientifically in exactly the same way we approach our organic being. What it is to possess a liver or a heart is something I can define quite independently of the space of questions in which I exist for myself, but not what it is to have a self or be a person" (Taylor, 1985b: 4). Taylor's hermeneutic perspective takes one's self-interpretations of themselves and reality as constitutive of what and who they are. These interpretations cannot be reduced to the status of epiphenomenons or 'subjective' emotions and thus not so legitimate accounts of reality (Taylor, 1985b: 47). Humans are self-interpreting creatures who exist in a social space that is defined by 'distinctions of worth.' A being who exists only in self-interpretation can never be understood absolutely. This, though, is what naturalist theories claim to be able to do by giving a strictly causal and empirical account of man in a value-free language. The modern disengaged self "aspires after a kind of neutrality. Disengagement entails a kind of neutrality in relation to what is disengaged from" (Taylor, 1988: 312).

However, we can never escape the very human predilections that frame how we look at reality, least of all when we deceive ourselves into thinking we are reflecting upon ourselves from a position outside of ourselves. This is because any and every "given explanatory framework secretes a notion of the good, and a set of valuations, which cannot be done away with – though they can be over-ridden – unless we do away with the framework. Of course because values can be over-ridden, we can only say that the framework tends to support them, not that it establishes their validity" (Taylor, 1985a: 90). Hence "whatever we might identify as a fundamentally common human nature, the possible object of an ultimate experience-transcending science, is always and everywhere mediated in human life through culture, self-understanding, language" (Taylor, 2002: 11). A being "who can only be understood against the background of distinctions of worth cannot be captured by a scientific language which essentially aspires to neutrality" (Taylor, 1985b: 3).

The key phenomena underappreciated by naturalist models are collective meanings that we all draw on in creating our self-understandings of the world and ourselves. The most important dialogical actions humans engage in are the learning of languages of self-expression. A spoken language like English or French contains common and intersubjective meanings that we as individuals play off in our attempts to understand ourselves, others, and the world in which we and they reside. Common meanings are objects in a given social world that all

participants in that world share such as collective practices, collective feelings like patriotism and what Taylor defines elsewhere as common goods (such as the preservation of Francophone culture in Taylor's native Quebec) that all members of a society partake of. "Inter-subjective meaning gives a people a common language to talk about social reality and a common understanding of certain norms" (Taylor, 1985a: 39). Naturalist social science models are unable to account for common and intersubjective meanings because they lack a conception of meaning for a subject who can be part of a we as well as an I (Taylor, 1985a: 40). At the same time, these models rely on intersubjective meanings for their accounts to make sense. The result is situations like 1960s theories of development in comparative politics where scholars strove to create value neutral or objective understandings of politics that can apply universally to all societies but which in fact are based solely on historically specific Western-centric intersubjective meanings. This produced ethnocentric theories of development that predictably placed Western democracies at the apex of development (Taylor, 1985a: 42).

Good social science should go beyond the mere bounds of empirical verification to study changes in social reality at the level of its foundational intersubjective meanings (Taylor, 1985a: 52). A hermeneutician like Taylor strives to do this by providing a clearer interpretations of a given social phenomena than the immediate understanding of agents involved in it. Hence the hermeneutician's understandings must in an important sense be 'out of phase with the explicandum' (Taylor, 1985a: 27). The problem though is that this out of phase explanation will itself be a force for change in the meaning of a given phenomenon to an agent as well as a possible change of that entity and a given social practice. Entities only have "meaning in a field, that is, in relation to the meanings of other things. This means that there is no such thing as a single, unrelated meaningful element; and it means that changes in the other meanings in the field can involve changes in the given element" (Taylor, 1985a: 22). Intersubjective meanings define these fields as well as the parameters for change as they define the semantical resources from which subjects can construct their own self-interpretations of the phenomena.

Taylor's Account of the Strongly Evaluative Subject

Taylor is well aware that concepts such as human rights are dependent upon some ontology of value that cannot be reduced to a utilitarian or mechanist understanding of human social life (Taylor, 2003: 310). Such understandings derive their value and legitimacy from a larger ontology of meaning supplied by the cultures and traditions from which they emerged, in this case the modern West. Heidegger and Merleau-Ponty taught Taylor that contra a mediational or representationalist epistemology, "our grasp of things is not something that is in us, over against the world; it lies in the way we are in contact with the world" (Taylor, 2004a: 38). Hence the subject-centered picture of mediational epistemology that has held 'us' captive since Descartes can be escaped via a deeper understanding of our thinking, which Heidegger and Merleau-Ponty provide (Taylor, 2004a: 40). For Taylor, humans are both engaged and disengaged creatures at once at the effect of causes and under the spell of reasons for action. We are always already coping with the world via our bodily commerce with it. Yet central to our modern sense of self is the ability to disengage from this engaged mode of being so as to see things from a universal or 'objective' viewpoint (Taylor, 2004a: 46). This is because a central feature of the modern identity as it comes down to us through history is its buffered characteristics. The modern self is a buffered self in that things, which lie outside the boundary of 'the self' do not necessarily need to affect the self. "This self can see itself as invulnerable, as master of the meanings that things have for it" (Taylor, 2011a: 41). In our disenchanted world, "the physical world, outside the mind, must proceed by causal laws that in no way turn on the moral meanings things have for us"(Taylor, 2011b: 62). By contrast the premodern self is a porous one in which the boundary between self and external forces is porous. The latter lived in an enchanted world where the meaning of something existed already outside of us, prior to contact (Taylor, 2011b: 61).

A modern can learn that he feels depressed because of hunger, hormones, or whatever thereby allowing him to take a critical distance from and potentially devalue this feeling. The modern emphasis on a mind/body dichotomy allows her to relegate the feelings of the body to a contingent set of physical forces that do not necessarily need to have sway over the actions of said self. "But a pre-modern may not be helped by learning that his mood comes from black bile. Because this doesn't permit a distancing. Black bile *is* melancholy. Now he just knows that he is in the grips of the real thing" (Taylor, 2007: 37).

Hence we are in a moral sense made by ontologies of meaning even as we try to be disengaged and reflective upon them – the drive to disengage and produce out of phase explanations is itself part of the ontic framework that we try to reflect on. Moments of attempted disengagement provide clearer (but never clear) understandings of who we are but do not literally disengage us from the moral ontologies that we cannot help but draw upon in crafting our identities.

These ontologies help to create a social imaginary; a common or background set of understandings, which makes possible a society's common practices of politics, morality, religion, and economics as well provide a widely shared sense of the legitimacy (or lack thereof) of these practices (Taylor, 2004: 23). A social imaginary, denotes "that largely unstructured and inarticulate understanding of our whole situation, within which particular features of our world show up for us in the sense they have. It can never be adequately expressed in the form of explicit doctrines, because of its very unlimited and indefinite nature" (Taylor, 2010: 309). For example, far from being free standing, a form of public reasoning like Rawls' is an expression of some family of moral values and those values are indeed synonymous with certain metaphysical and ethical assumptions about human subjectivity, dignity, and the like. The model only becomes coherent by tacitly invoking a set of intersubjective and common meanings synonymous with the modern social imaginary.

Nevertheless these ontologies and the social imaginary they constitute are historical creations. Given the disengaged nature of modern existence, a crucial task for contemporary social scientists is to understand the diversity of moral goods that comprise the modern social imaginary and the ontologies of

meaning like the modern moral order that make us who we are even as we reflect upon and critically distancing ourselves from them. This entails freeing ourselves from philosophical systems that are either predicated upon a disengaged relationship between a subject and an object, or, like Marxism, that recognize only one genre of values and only one manner of interpreting reality (Taylor, 1985: 247). By doing so, we can open ourselves up to the diverse array of moral goods that we unavoidably invoke within our daily lives.

Taylor's Understanding of the Modern Social Imaginary

Taylor's most important works *Sources of the Self* and *A Secular Age* are attempts at articulating not only these goods but also the manners in which they combine to frame the most important moral and political conflicts at play beneath the modern social imaginary. *Sources of the Self* narrates the rise of our modern life goods and the moral sources that inform them as well as the subsequent development of the conflicts between these life goods. Taylor also distinguishes three aspects of (but what could more accurately be described as three movements in) the development of the modern social imaginary: "First, modern inwardness, the sense of ourselves as beings with inner depths and the connected notion that we are 'selves'; second, the affirmation of ordinary life which develops from the early modern period; third, the expressivist notion of nature as an inner moral source"(Taylor, 1989: x). The first movement extends from Augustine through Descartes and the original Christian turn inward. Taylor traces the second movement, the affirmation of ordinary life, "from the Reformation through the Enlightenment to its contemporary forms" (Taylor, 1989). The third Taylor depicts as originating with the Romantic Movement in the late-eighteenth century and then developing via modernist art, nineteenth-century thinkers like Schopenhauer, Baudelaire and Nietzsche, and later twentieth-century literature.

Taylor's depiction of these three movements leaves him with what he admits is an overly schematic map of the historical origins of our modern moral sources. The key point about this map is that the three domains are fluid as they are continually borrowing from and influenced by each other. Hence our life goods often draw from more than one set of moral sources and find their origins in multiple historical movements. For example, the ethic of benevolence, a product of the affirmation of ordinary life, draws on two sources: the ideal of disengaged reason and autonomous subjectivity and a conception of nature, which one would normally associate with the expressivist genre of constitutive goods. What Taylor calls the ethic of authenticity was a product of the romantic era's critique of Enlightenment forms of reasoning and its yearning for seemingly disavowed senses of community. However, the ethic also owes much of its development to the modern turn inward. Furthermore, most plausible notions of self-realization or authenticity presuppose – following the third spiritual set of constitutive goods – that some goals or aspirations that link the individual to something greater than self-interests.

A prominent criticism of *Sources of the Self* is that Taylor never actually shows us why or how the constitutive or life goods of modernity are actually embodied in the actions and lives of actual living human beings and hence why *Sources of the Self* has indeed provided us with the best account of 'our' moral order.

This problem is somewhat rectified in *A Secular Age* and the works that accompanied it. One of these related works *Modern Social Imaginaries* (a shorter version of which is a chapter in *A Secular Age*) provides a story of how a set of ideas initially wrapped up in the discursive practices of the seventeenth-century natural law tradition of Grotius and Locke becomes transformed by modern and contemporary intellectuals and along the way drives the development of the modern moral order with its practices of civility, the market economy, the public sphere, and the practice of democratic self-rule. These practices embody many of the life goods, such as autonomy, equality, disengaged reason, and the affirmation of ordinary life Taylor chronicles in *Sources* (Taylor, 2004b). In *A Secular Age* this story then complements other stories on Christian reform movements, the emergence of deism and eventually modern humanism and the growth of modern disciplined and disengaged notions of subjectivity to give us a picture of the modern social imaginary. More specifically, the stories collected in *A Secular Age* chronicle the development of contemporary secularity through a series of redactions that make it increasingly more inclusive, richer (in its contents) and demanding (in its requirements on modern Western subjects) as Western modernity progresses from its genesis in the seventeenth century to its present incarnations.

Abstract

A multitude of empirical studies have documented that teacher effectiveness impacts student learning, and the impact is of magnitude that is larger than the effects associated with financial investment, class size, curriculum, school restructuring, and many other educational interventions. Teachers matter. Becoming an effective teacher is not simple. Teaching is a complex form of work. It involves a specialized, intricate, and constantly changing and renewing body of knowledge and skills. Nonetheless, there are common attributes that characterize effective teachers. This article summarizes the common background and identifies the qualities, dispositions, and behaviors of effective teachers that emerged in a careful review of the extant literature.

Teachers and Teaching

Teachers, as the most powerful school-related factor, matter massively to student learning outcomes and school performance. Indeed, among the factors within the control of school systems, teachers offer the greatest opportunity for improving the quality of life of students. As noted in *How the World's Best-Performing School Systems Come Out on Top*, an international study comparing data from the OECD's Programme for International Student Assessment, "The quality of an education system cannot exceed the quality of its teachers" (Barber and Mourshed, 2007: p. iii).

The research suggests that "while schools have powerful effects on student achievement differences, these effects appear to derive most importantly from variations in teacher quality" (Hanushek et al., 1998: p. 1). With the development of sophisticated statistical modeling involving longitudinal data, researchers have been able to isolate effects on student achievement and one theme emerges: the effect of the classroom teacher. A multitude of studies conducted in the United States have documented that teacher quality has a significant impact on student achievement (Stronge et al., 2011). Based on a review of the literature, qualities related to effective teaching include background characteristics of teachers, teacher dispositions, lesson planning, the classroom environment, lesson delivery, and classroom assessment.

Background Characteristics

Presage Teacher Characteristics

Presage variables are "properties of teachers that can be assumed to operate prior to, but also to have an influence on, the interactive phase of teaching" (Rowan et al., 2002: p. 1538). The most widely studied presage variables include certification status, teaching experience, content knowledge, degree, coursework, verbal skills, subject-matter knowledge, academic achievement, and the prestige ratings of teachers' undergraduate institutions. Collectively these presage – or background – qualities do appear to be important in terms of teacher effectiveness. Specific teacher presage qualities and their relationship to student achievement that will be explored briefly include: teacher degrees earned, coursework, certification status, content knowledge, teaching experience, and verbal ability.

Degrees Earned

Degree level and area of degree attained by the teacher have been widely examined in quantitative studies. Generally, the research has been inconclusive as to how degrees contribute to teacher effectiveness. Several studies found no statistically significant effect of teacher degree level on teacher effectiveness as measured by student achievement gains, while controlling for confounding effects of student background and other teacher-related characteristics (e.g., Wayne and Youngs, 2003). On the other hand, others have found statistically significant effects of teachers' degree status on growth at the elementary and secondary levels in reading and mathematics (e.g., Rowan et al., 2002).

Coursework

Another teacher attribute that is closely related with degree is teachers' course-taking. Over the last several decades, policy makers and researchers have used measures of the level and type of coursework taken by teachers as proxies for what teachers know and can do in their classrooms. Individual studies and syntheses of literature have found that coursework-taking has a positive effect on student achievement and these effects are seen in high school mathematics and science (Monk, 1994; Rice, 2003). However, in other subjects and grade levels, the impact of teacher content course-taking on student achievement was found to be indeterminate and inconsistent.

Certification Status

Historically, policy on teacher certification has been used as an important leverage to manipulate the quality of the teaching profession, and it is one of the most widely tested teacher attributes in educational research. The extant evidence indicates a relationship between certification in mathematics and students' high school mathematics achievement (Goldhaber and Brewer, 1997) but at the elementary level. Findings from

different value-added studies have yielded inconsistent results (Rowan et al., 2002; Palardy and Rumberger, 2008).

Types of teacher certification also have been studied at several levels. These studies have found consistent evidence that teachers with standard certification have more of a positive impact on student achievement than teachers with emergency or no certification (Darling-Hammond et al., 2005; Goldhaber and Brewer, 2000).

Content Knowledge

A teacher's understanding of subject facts, concepts, principles, and the methods through which they are integrated cognitively determine their pedagogical thinking and decision-making. Studies have found consistent results in that content knowledge and pedagogical content knowledge on the part of the teacher are crucial for student success in mathematics (Harris and Sass, 2007; Hill et al., 2005). Most studies related to content knowledge have focused on mathematics and therefore it is difficult to draw conclusions about the effects of content knowledge in other content areas.

Teaching Experience

Teacher experience is a crucial criterion for teacher compensation in most public school systems, and policy makers and researchers have shown increasing interest in investigating its impact on student achievement. Putting available evidences together, it seems that the relationship between years of teaching and teacher expertise is nonlinear. Teachers' experience matters only for the first few years of teaching – most definitely, the first 3 years. During these first few years, teachers appear to gain cumulatively in their contribution to student learning and, then, after three or so years, the contribution of experience to student learning levels off (Rivkin et al., 2005). Nonetheless, there are contradictory findings regarding the relationship between teaching experience and teacher effectiveness.

Teacher Verbal Ability

One key finding that has emerged from an analysis of teachers' background qualities is that students taught by teachers with greater verbal ability learn more than those taught by teachers with lower verbal ability (Rowan et al., 1997). Teaching is, among other things, explaining and is a verbal process. Thus, a discernable link appears to exist between effective teachers' verbal clarity and student academic achievement.

Teacher Dispositions

Although teachers vary significantly in their ability to improve student achievement gains, little of this variation can be attributed to observable characteristics such as degree and teaching experience (Rivkin et al., 2005). For instance, Goldhaber (2002) pointed out that only about 3% of the contribution teachers make to student learning is associated with teacher experience, educational level, certification status, and other readily observable characteristics. The remaining 97% of teachers' effects on student achievement are associated with intangible, unobserved aspects of teacher quality such as dispositions, attitudes, and classroom practices. Critical teacher dispositions that emerge in the literature include caring, a sense of efficacy, motivation and enthusiasm, and professional growth.

Caring

Caring about students and respecting them as individuals are prevalent in the literature descriptions of effective teachers (Cassidy and Bates, 2005; Noddings, 1992). Good teachers are often described as warm, friendly, and caring; conversely, ineffective teachers often are said to create a tense classroom and are described as cold, abusive, and uncaring (Walls et al., 2002). In classroom learning, when students are supported by a caring teacher, they are more likely to ask questions, take chances, and share their inner thoughts in creative writing and through other forms of expression (Cassidy and Bates, 2005).

Exemplary teachers regard the ethic of care and respect as a vital foundation for students' best learning and a prerequisite for effective teaching. They reach out to know their students by using multiple sources of knowledge (e.g., solicited critique, dialogues and questions, knowing students informally, knowing from colleagues, and knowing students' cultures) (Collinson et al., 1999).

Efficacy Beliefs

Self-efficacy refers to the belief in one's ability to accomplish intended outcomes. This belief influences an individual's behavior, motivation, effort, ultimately their success or failure. The reviews of research on teacher self-efficacy have summarized that teachers' self-efficacy was linked to teaching practices in their classrooms and student outcomes such as students' self-efficacy beliefs and student engagement, motivation, and achievement (Tschannen-Moran and McMaster, 2009). Compared to teachers with lower self-efficacy beliefs, teachers with stronger perceptions of self-efficacy tend to use more challenging teaching techniques, try innovative strategies, and employ classroom instruction that are more organized and better planned, student centered, and humanistic (Tschannen-Moran and Hoy, 2001). Efficacy is also a personal resource that can protect teachers from experiences of job stress and burnout (Schwarzer and Hallum, 2008).

Motivation and Enthusiasm to Teach

Motivation and enthusiasm are contagious in classrooms. Teachers who are more enthusiastic about teaching exhibit higher quality instructional behaviors, such as monitoring student learning, providing students with more autonomy support, offering more social support to students, and using higher levels of cognitive challenge. Teacher motivation also is expressed in a range of teacher behaviors that are perceived to be conducive to student learning, such as enthusiasm in content area taught, interest about students' personal and developmental needs, participation in content-related activities outside of class time, and displaying value and emotion for students (Long and Hoy, 2006).

Teachers who display enthusiasm and energy in the classroom often increase student interest and motivation to learn.

Among various teacher variables, enthusiasm was the most powerful unique predictor of students' intrinsic motivation and vitality. The students who received instruction from an enthusiastic teacher reported greater intrinsic motivation regarding the learning material and experienced higher levels of vitality (Kunter et al., 2008). Students who are under the tutelage of motivated and enthusiastic teachers are more likely to be enthusiastic toward the subject and exhibit higher rate of on-task behavior (Bettencourt et al., 1983).

Professionalism and Professional Growth

Another key attribute of effective teachers is a commitment to continuous improvement and perpetual learning. Evidence indicates that teachers who receive substantial professional development can help students achieve more. For example, based on the findings of one meta-analysis, teachers who receive substantial professional development (in this instance, 49 h) can boost their students' achievement by about 21 percentile points, and this effect size is fairly consistent across content areas (Yoon et al., 2007).

Lesson Planning

Teaching is a complex activity that involves careful preparation and planning, both for short-term and long-term learning purposes. Looking at national level teaching standards in the United States, such as the Interstate New Teacher Assessment and Support Consortium (InTASC) (2013) and the National Board for Professional Teaching Standards (NBPTS) (2012), instructional planning is a key aspect of any teacher's work in order to give students meaningful learning experiences. Among key attributes of effective teachers' planning are: making instruction a priority in teaching practices, holding high student expectations, developing planning routines and automaticity, providing clear learning objectives, creating quality assignments, and planning for instructional sequencing and curricular alignment. Each of these attributes in relation to the behaviors of effective teachers will be explored, in turn. (A significant portion of this article on effective teachers and instructional planning is adapted from a research review conducted by Jessica Straessle as part of her dissertation at the College of William and Mary with permission.)

Making Instruction a Priority

One of the best ways to maintain a focus on instruction is for teachers to have a written plan. Written lesson plans provide teachers with an opportunity to connect learning goals to activities, allocate time to complete those activities, and remove any foreseeable obstacles to instruction. Well-organized and thoughtfully constructed lesson plans help teachers become more effective leaders in the classroom and enable them to make more efficient use of class time (Panasuk et al., 2002). Effective use of class time helps teachers maintain focus on specific learning goals, since lesson plans provide a blueprint for instruction that allows teachers to allocate time for academic instruction.

Instructional Planning and Teacher Expectations

The beliefs that teachers have about their students' abilities can profoundly affect both teacher and student performance. Low expectations impact teacher efficacy, student behavior, and student achievement (Wentzel, 2002). Studies indicate that teachers can hold differing expectations based for wealthy versus poor students and poor students in urban settings (Auwarter and Aruguete, 2008; Warren, 2002).

Routines and Automaticity

In Yinger's (1980) study of teacher planning, he found that routines played a major role in a teacher's planning. Routines were used by the teacher to regulate activities and to simplify planning. In fact, he found that routines were so much a part of planning that he described planning "as decision-making about the selection, the organization, and the sequencing of routines" (p. 111). Hattie (2009) also discussed routines and the need for teachers to have routines in order to be experts. Listed under the dimension of *Monitoring and Providing Feedback*, Hattie (2009) determined that expert teachers are more automatic than nonexpert teachers.

Clear Lesson and Learning Objectives

Among the many decisions a teacher must make, research indicates that planning for effective teaching includes identifying clear lesson objectives (Stronge, 2007). Objectives provide a preliminary guide for planning (Marzano, 2007). Effective teachers provide a short statement of goals that provide focus for the instructional process.

Creating Quality Assignments

Developing clear learning objectives is merely an early step in instructional planning for effective teachers. Creating quality assignments is another characteristic of an effective teachers' lesson planning. In practice, they recognize that the assignment is just as important as the objective as it is the means to the end. The idea that clear objectives, followed by quality assignments, lead to student achievement, should make sense. Studies have found significant relationships between quality of classroom assignments and quality of student work (Clare, 2001; Koh and Luke, 2009).

Instructional Sequencing

Sequencing is another important aspect of logically structuring lessons for effective teachers. The teacher sets students up for success by identifying a sequence and ensuring that the knowledge gained is based in grounded ideas and building from that point. Good and Brophy (2008) found effective teaching requires that teachers plan sequences of lessons and do not plan in isolation.

Instructional Alignment

Alignment goes hand in hand with sequencing in enhancing teachers' planning practices. It is important for lesson planning

to be sequential, and within the sequence there must be alignment in all aspects – particularly the learning objective, activity, and evaluation. This alignment ensures that students are engaging in activities which support the learning objective and are being evaluated on the same learning objective.

Learning Environment

Caring, supportive, safe, challenging, academically robust: these attributes help define what it means to have a positive learning environment that is conducive to student success. The most prevalent criteria used to define learning environment are probably the physical arrangement of the classroom, discipline, and routines; organization of learning activities; and the engagement of students with tasks, among others (Cameron et al., 2008). Students need an engaging, stimulating, and enriching learning environment to grow and thrive. In order to achieve this type of rich environment, effective teachers establish and communicate guidelines for expected behavior; monitor student behavior; keep students on tasks; and infuse humor, care, and respect into the classroom interactions, so as to develop a climate that contribute to student learning (Kunter et al., 2007).

As a result, research has indicated that a positive learning environment can shape student outcomes in cognitive, motivational, emotional, and behavioral domains (Ludtke et al., 2009). Wang et al. (1994) analyzed a knowledge base comprising 11 000 statistical findings connecting a variety of variables and student achievement in order to answer the question: *What helps students learn?* Twenty-eight categories of factors, classified into six broad types of influences (i.e., student aptitude, classroom instruction and climate, context, program design, school organization, state and district characteristics), were scored based on their positive impact on learning. Of the 28 categories, classroom management ranked first and was the most influential variable, just ahead of student metacognitive processes and cognitive processes. In the researchers' view, "effective classroom management increases student engagement, decreases disruptive behaviours, and makes good use of instructional time" (p. 76).

Classroom Routines and Procedures

Classroom management includes actions taken by teachers to establish order, engage students, elicit student cooperation, with an ultimate purpose to establish and maintain a setting conducive to instruction and learning. Effective teachers were found to maintain their management system by monitoring and providing prompt feedback, and by consistently applying classroom procedures and consequences (Emmer and Stough, 2001). Stronge et al. (2008) found that compared with bottom-quartile teachers, top-quartile teachers (as determined by their ability to effect student achievement gains) were more organized than ineffective teachers with efficient routines and procedures for daily tasks. And they communicated higher behavioral expectations to students. The top teachers also were found to have less disruptive student behaviors (once every 2 h) than did the less-effective teachers (a disruption every 12 min). Researchers also noted that teachers who spend more time establishing instructional routines at the beginning of the school year did not need to exert as much effort on similar tasks later in the year (Cameron et al., 2008).

Physical Arrangement of the Classroom

Effective teachers develop functional floor plans with teacher and student work areas and furniture/materials placement for optimal benefit (Stronge, 2007). LePage et al. (2005) contended that an orderly classroom arrangement optimizes learning time, whereas inadequate planning causes disruptions and delays. Additionally, arranging the classroom carefully and thoughtfully supports orderly movement, minimizes distractions, and provides for efficient use of available space.

Positive Classroom Climate

Effective teachers build a classroom climate where error (i.e., risk-taking) is welcomed, student questioning is high, engagement is the norm, and students can gain reputations as effective learners (Hattie, 2009). Positive classroom climate has been found to be related to important educational outcomes such as enhanced academic achievement, constructive learning processes, and reduced emotional problems. Nevertheless, classroom climate can also be negative and toxic and related to undesirable outcomes, such as increased bullying and aggression and social and emotional maladjustment (Evans et al., 2009).

Classroom Talk

The interaction between teacher and students, and among students, is another significant indicator of learning environment. Authority is more distributed than centralized in a positive classroom environment. Additionally, the talk between teacher and student is personalized and personal. Exemplary teachers have been found to use authentic conversation to learn about students and encourage students to engage their peers' ideas (Allington and Johnston, 2000).

Instructional Delivery

Instructional delivery is a process in which teachers apply a repertoire of instructional strategies, to communicate and interact with students around academic content, and to support student engagement. An array of studies has found that the actual practice of teaching is a critical factor for student learning (e.g., Palardy and Rumberger, 2008). Teachers with the same background qualifications and same schooling resources do different things in their classrooms and, consequently, enable their students to achieve at different levels. To discover what makes a teacher effective, one needs to look into the black box of the classroom and see how teachers translate their content knowledge, pedagogical skills, and resources into opportunities for student learning.

Cohen et al. (2003) argued that the key causal agents for student achievement reside in instruction, and teachers' classroom teaching has the most immediate causal effects on student learning compared with other school-related factors. A

similar point was made by Palardy and Rumberger (2008). They noted that of three aspects of teachers discussed in the literature (i.e., background qualifications, personal dispositions such as attitudes, and instructional practices), instructional practices have the most proximal association with student learning. That is, "instructional practices are theorized to influence student learning directly, whereas teacher background qualifications and teacher attitudes are theorized to influence learning indirectly through their association with instructional practices" (p. 115). From a review of the literature, the following areas emerge as key instructional delivery practices.

Differentiation

Instead of using uniform strategies for all students, effective teachers design instruction that motivates each student and they communicate content in such a way that students are able to comprehend based on their individual prior learning and ability. Because students learn in a variety of ways and at a variety of rates, teachers should deliver their lessons with appropriate variety, also. A meta-analysis of the extant research suggests that instruction based on learning styles is positively related to student attitudes and achievement (Lovelace, 2005). Dunn et al. (2009) extended this finding to at-risk students, reporting that mean achievement increased nearly one standard deviation (i.e., approximately 84th percentile 50th percentile) when teachers accommodated for learning styles. Implementing a variety of classroom techniques and strategies also enhances student motivation and decreases discipline problems (Dolezal et al., 2003). Furthermore, differentiated instruction enables teachers to adjust their curriculum, materials, learning activities, and assessment techniques to ensure that all students in a mixed-ability classroom can have different avenues to process new knowledge and develop skills, while having equal access to high-quality learning (Tomlinson, 2001).

Cognitive Challenge

The teacher provides in-depth explanations of academic content and covers higher-order concepts and skills thoroughly (Wenglinsky, 2002). Kunter et al. (2008) found that teachers who engaged students in higher levels of cognitive challenge were more enthusiastic about teaching and therefore engaged in high-quality instructional behavior.

Student Engagement

In a more recent review of the literature, researchers found that student engagement is crucial for student learning, varies over time, and can be positively or negatively impacted (Finn and Zimmer, 2012). The teacher is supportive and persistent in keeping students on task and encouraging them to actively integrate new information with prior learning. In addition, the teacher uses effective questioning, smooth transition, and challenging but interesting activities to increase student engagement in learning and student accountability (Cotton, 2000; Wang et al., 1994).

Questioning

Questioning can be another highly effective instructional tool when used properly (Guo et al., 2007). In particular, the types of questions asked, wait time, and types of responses play a role in the propitious use of questioning (Walsh and Sattes, 2005). There are substantial differences in the adept use of questioning between effective teachers and ineffective teachers. On the negative side, in a study of mathematics classrooms Craig and Cairo (2005) found that teachers ask more than 99% of the questions. They also found that teachers tended to provide little wait time, asked recall and use questions, and designated a particular student to answer a question. On the positive side, one case study found that teachers deemed effective asked approximately seven times more higher cognitive-level questions than those considered ineffective (Stronge et al., 2008).

Relevance

Making instruction relevant to real-world problems is among the most powerful instructional practices a teacher can use to increase student learning (Schroeder et al., 2007; Wenglinsky, 2004). This kind of instruction allows students to explore, inquire, and meaningfully construct knowledge of real problems that are relevant to their life. Moreover, students are motivated and engaged when their learning is authentic, especially when the real-world tasks performed have personalized results.

Assessment of and for Learning

The practice of assessing student progress is essential for effective instruction and learning. High-quality assessment provides teachers with the information regarding the extent to which students have attained the intended learning outcomes, and it informs teachers' instructional decision-making (what to teach and how to teach) as well. Assessing student learning involves engaging in formative assessment practices, monitoring student progress and making decisions based on the progress, and providing meaningful feedback.

Formative Assessment

Over the past 20 years, research out of the Assessment Reform Group has informed and heightened a focus on the importance of assessment in the classroom. Research has indicated that teachers who introduce formative assessment into their classroom practice can affect substantial achievement gains. In their 1998 research review, Black and Wiliam (1998) examined a multitude of empirical studies to determine whether improvement in classroom assessments can lead to improvement in learning. They found that formative assessment has substantial positive effects on student achievement, with effect size ranging from 0.3 to 0.7 standard deviations. Particularly, they found that formative assessment is more effective for low achievers than other students, thus, reducing an achievement gap while raising achievement overall at the same time.

Progress Monitoring

Student progress monitoring is a practice that helps teachers use student performance data to continuously evaluate the effectiveness of their teaching and make more informed instructional decisions (Safer and Fleischman, 2005). Fuchs et al. (1984) used an experimental design to investigate the effects of frequent curriculum-based assessments. Analyses indicated that

- teachers in the experimental group, who adopted systematic assessment procedures, effected greater student achievement than those who used conventional monitoring methods;
- teachers in the experimental group had more improvement in their instructional structure; and
- experimental teachers' pedagogical decisions reflected greater realism and responsiveness to student progress.
- The students taught by experimental teachers were more knowledgeable of their own learning and more conscious of learning goals and progress.

Student progress monitoring facilitates teachers tracking students' academic growth on a regular basis. It can continually provide teachers with the data and evidence about students' performance to evaluate the effectiveness of their instruction and make adjustments in their pedagogical behavior.

Teachers who monitor their students' progress exhibit greater concerns about student learning and higher academic emphasis in their instruction. They also are better at supervising the adequacy of student learning, identifying students in need of additional or different forms of instruction, and determining what instructional modifications are necessary. Progress monitoring also can help teachers set meaningful student achievement goals to tap into greater student potential of learning. Empirical research found that when progress monitoring is combined with goal-setting, student learning profiles, and appropriate instructional modifications, it could help teachers build stronger instructional programs that are more varied and more responsive to students' learning needs, and effect better academic performance for students (Fuchs and Fuchs, 2003).

Feedback

Feedback is part of the formative assessment process and has emerged as a crucial part of a teacher's work. Hattie (2009) found that compared to their ineffective colleagues, effective teachers were adept at monitoring student problems and assessing their level of understanding and progress, and they provided much more relevant, useful feedback. Indeed, after reviewing meta-analyses of the myriad possible influences on student achievement, Hattie (2009) found that feedback was one of the most significant with an effect size of 0.73.

Conclusion

Studies on teacher effectiveness provide some insights into the qualities that connect teacher effectiveness and student achievement. The outcomes of these studies, while informative, have not led to a standard definition of teacher effectiveness. Neither have they generated a commonly agreed-upon list of effective teaching qualities. Generally, effective teachers plan carefully, use appropriate materials, communicate goals to students, maintain a brisk pace, assess student work regularly, and use a variety of teaching strategies. They use class time well and have coherent strategies for instruction. They hold the expectations that their students can learn and believe that they have a large responsibility to help (Cohen et al., 2003). This list is far from complete. In essence, teaching is a highly complex work with a multitude of teacher-related, as well as other, variables that affect student success. However, one clear message emerges from the literature: the impact of the teacher on student learning.

Abstract

This article traces the development of teacher education and in particular identifies a number of key debates and tensions that emerge from that history and are still relevant today. These include the nature of professional knowledge, the sites for learning, and the relationship between preservice, induction, and continuing professional development. The quality of teaching is now seen to be a key factor in the success of educational systems and the nature of teacher preparation and development has assumed great significance in the twenty-first century.

Introduction

In the early twenty-first century, teacher education has become a key focus within education systems across the world. This reflects growing international concern about the importance of the quality of teaching and recognition that this in turn is likely to be dependent on the quality of teacher preparation and teacher development.

This recent renewed interest in the importance of teaching and teacher education builds upon a long history of the development of institutional approaches to the preparation and ongoing development of teachers. This article therefore commences by offering a review of this history, exploring how the development of the teaching profession related to the arrangements for teacher education. Consideration is then given to a number of key issues in teacher education, as currently constructed, such as the variety of routes of entry into the profession, the significance of the contribution of different sites of learning for teachers, and the idea of teacher professional development and learning as a career-long continuum. Finally we reconsider the connections between teacher education and the globalization of education and the latest developments in 'integrated' approaches, which seek to develop teaching as a research-oriented profession.

History

There is no single history of teacher education around the world. There are notable differences between continents as well as within continents (e.g., Dent, 1970; Sedlak, 2008). Until the nineteenth century, however, it would be reasonable to suggest that the teaching profession was closely associated with universities and with religious organizations. It was the emergence of state provision for schooling in the late nineteenth century that led to the rapid expansion of systematic approaches to the preparation of teachers in many locations. In particular the establishment of 'normal schools' was a feature in Europe as well as in North America. These schools not only provided education for children but were also the sites for an apprenticeship style of training for prospective teachers.

As state education systems expanded, so Colleges of Education began to emerge, enabling the creation of larger classes of study for trainee teachers and sometimes the provision of experimental classrooms or schools where groups of trainees could observe teaching and be evaluated by others in their own teaching.

The twentieth century saw the rise of social science disciplines including psychology and sociology and the contribution that these subjects might make to the education of teachers was recognized. So we began to see the steady 'academization' of teacher education, the introduction of a body of specialized professional knowledge that was judged to be important. As this process continued, so the direct involvement of universities in teacher preparation increased (see Alexander et al., 1984). This was sometimes through the processes of validation or accreditation of teacher education programs but also increasingly through direct provision of programs by universities.

This in turn was associated with an increasing 'professionalization' of teaching and thus, for example, in England we saw by the early 1970s the call for teaching to become an 'all-graduate' profession (James, 1972). So, while many secondary schoolteachers had a first degree before they entered teacher training, many teachers working with younger children had entered teaching with some form of certificate that had not led to a degree as such. But this development saw the emergence of Bachelor of Education degrees as a major route into teaching for primary teachers, as well as for some secondary schoolteachers.

At the same time as this was happening, a large number of Colleges of Education were being amalgamated in a program of 'rationalization' and then were being incorporated into universities or polytechnics. The polytechnics themselves were converted into universities late in the twentieth century, so that by the end of the twentieth century, teacher education – especially initial or preservice teacher education – may be seen to have gone through a process of 'universitization' (Menter et al., 2006).

While the move toward the academy as a key contributor to the education of teachers was a common trend in most parts of the world, the late twentieth century saw some quite significant disruption in this trajectory. In the United States and in England in particular there has been a surge in the introduction of 'alternative' routes into teaching. Sometimes these have arisen in the context of teacher shortages, that is the supply of teachers failing to meet the numbers required by the schools, but quite often these innovations have been associated with ideological critiques of the nature of university-led teacher education. These themes will be picked up later in this article.

The focus on teacher education has been intensified by the publication of a number of transnational reports on teaching and attainment. The Programme for International Student

Assessment studies published by the Organisation of Economic Cooperation and Development (OECD) have heightened policymakers' concerns about the attainment of young people in core subjects across the world. The OECD has also been carrying out an international survey TALIS (Teaching and Learning International Survey), which has offered comparisons of the experiences and needs of teachers across many nations (OECD, 2009). Research from the school improvement and school effectiveness movement has indicated that the quality of teaching is a key factor in raising school level attainment and then transnational reviews, especially those carried out by the McKinsey corporation (McKinsey and Co., 2007; Barber and Mourshed, 2009) have suggested that the quality of teaching is one aspect where politicians may have a real impact on the quality of their schools.

Entry Routes into Teaching

The history of teacher education has seen a wide range of approaches to entry into the teaching profession. During the twentieth century the move to professionalize did lead to some consolidation of the association of teacher preparation with formal academic qualifications. So, in Britain and North America, the emergence of qualifications such as Bachelor of Education or Postgraduate Certificate in Education (PGCE) was seen as providing a recognized teaching qualification. However, the route through which these could be achieved did vary considerably.

The first distinction to be made is between the undergraduate and postgraduate route. Undergraduate entry is aimed at people who have not yet got a first degree and who have decided before doing so that they do want to become teachers. Whereas a postgraduate route is for people who have undertaken a first degree (typically a BA or BSc) and now wish to spend time preparing to become a teacher.

The undergraduate routes may be divided into two main types, described as concurrent and consecutive. A concurrent degree would involve the student undertaking study and practice of education throughout the program at the same time as studying a specialist subject at degree level. By contrast a consecutive degree would involve studying the specialist subject for a period of time – perhaps 2 years, followed by another period during which the emphasis is on professional preparation for teaching, this involving placement in school as well as study of education. The professional parts of such programs typically have three main components, educational studies, subject pedagogy, and the practicum.

In postgraduate programs, which are typically less than 1 year long, one would not expect to see separate study of the subject but only of the three professional components, as set out above.

As mentioned above, however, the recent diversification of routes has added much more variety to what is offered. So, we have seen the shortening of degree entry routes in some places. Where a BEd with Honors in the United Kingdom was traditionally 4 years long, in England there have been shortened routes of 3 or even 2 years. Some routes, especially postgraduate routes, have sometimes been available for part-time study – although there is usually a full-time practicum element at some stage.

However, even greater variation has arisen from school-based or employment-based routes. In the United States we have seen 'alternative certification' entry being offered in some states or in England we have seen 'School-Centred Initial Teacher Training Schemes' and more recently 'School Direct (salaried)' programs in which the school takes the lead and in the latter case at least, the trainee is actually an employee at the school during their training and may expect to continue to work in the school once they have qualified.

Another variation on employment-based routes is seen in the form of Teach for America (US) or Teach First (England), schemes that are sponsored by major corporations and seek to attract people into teaching, at least for a short period, who might otherwise not have entered. The English version of this scheme has a strong emphasis on training teachers in settings where there is significant social disadvantage. The scheme aims to challenge such disadvantage by recruiting the most able students from the best universities and bringing about change in the schools (see Wigdortz, 2012). In the case of Teach First, the training does involve some university provision, including a preparatory 6-week summer school as well as continuing support from university staff.

At the same time as there have been moves to shorten routes of entry and reduce the input from the university, there has been a contrary trend in some settings, to increase the academic-level entry requirements. In some countries, Finland being a notable example, teaching has moved beyond being a degree-level entry profession to being at Master's level. Teaching is a highly esteemed occupation in Finland and admission to teacher education programs is highly competitive. The program of training is led by universities, each of which works in association with university training schools. Programs of study incorporate a research study and lead after 4 years to a Master's award (Sahlberg, 2012).

In the United Kingdom, there were significant moves in this direction in the early part of this century. Many PGCE awards now include a proportion of Master's level work and so newly qualified teachers emerged with a certain number of 'M Level' credits that they can then use as the basis for further study toward a Master's award.

Sites of Learning in Teacher Education

Many of the debates about the form and structure of teacher education programs have centered on questions about the nature of teaching and what forms of knowledge, skills, and experience are required in order to fulfill this definition. In a review of literature of teacher education in the twenty-first century, Menter et al. (2010) suggested that it is possible to identify four paradigms of teaching, each of which will lead to rather different approaches to the formulation of pre-entry programs. These are effectively 'ideal types,' which may not exist in a pure form in any given context and indeed actual models of teaching deployed in teacher education programs are likely to draw on more than one of them:

1. The effective teacher – with an emphasis on technical skills.
2. The reflective teacher – with an emphasis on values and review.

3. The inquiring teacher – with the adoption of a research orientation.
4. The transformative teacher – with the adoption of a 'change agency' approach.

Moving from the first to the fourth, each paradigm incorporates those with a lower number but builds upon it. These might be seen as positions on a spectrum of professionalism, which using the terminology developed in the 1970s by Hoyle (1974) moves from 'restricted' professionalism at one end to 'extended' professionalism at the other.

At the restricted/effective end of the spectrum, there is a view that the best place to learn to teach is alongside an experienced and successful teacher, through an apprenticeship model. This is sometimes depicted as a 'craft' view of teaching.

The skills of teaching are learned by observation and by imitation and in turn by being observed and receiving feedback from the experienced teacher. On this model, knowledge of the subject content of the teaching is assumed to be present; in other words the trainee is already well versed in the subject and all they require is enthusiasm and an ability to learn from observation and feedback. If this is a limited view of becoming a teacher for a secondary schoolteacher of a particular subject it is even more challenging for the elementary or primary schoolteacher whose subject knowledge will need to range right across the school curriculum. This position has been well exemplified by a recent Secretary of State for Education in England, Michael Gove, in his foreword to a Government White Paper:

> Teaching is a craft and it is best learnt as an apprentice observing a master craftsman or woman. Watching others, and being rigorously observed yourself as you develop, is the best route to acquiring mastery in the classroom.
>
> DfE, 2010

The developments in teacher education curricula which took place over the twentieth century led to the proposition that teachers actually need a range of forms of professional knowledge, including pedagogical knowledge and subject-related pedagogical knowledge, in addition to 'pure' subject knowledge. That is, teachers need to have knowledge not only of their subject but of how their subject is best taught and learned as well as more general knowledge about teaching and learning. On this view teaching is a much more complex activity involving numerous challenging judgments and decision-making in planning, implementing, and evaluating classroom interaction. This position is actually closely aligned with that taken in a recent review of teacher education in Scotland, carried out by the former Chief Inspector, Graham Donaldson, who saw teachers as

> … reflective, accomplished and enquiring professionals who have the capacity to engage fully with the complexities of education and to be key actors in shaping and leading educational change.
>
> Donaldson, 2011: 4

The debates about the kinds of professional knowledge needed by teachers influence not just the content of the teacher education curriculum but the locations in which professional learning takes place. Over the twentieth century there was in all teacher education programs some balance of provision between academic study and professional experience. This was sometimes posited as a balance of theory and practice, although this we shall argue is a simplistic distinction as in the most mature programs what is achieved through an appropriate balance between and integration of learning in different sites is a form of 'practical theorizing' (Hagger and McIntyre, 2006). This debate in teaching is also informed by a wider sociological discussion about the nature of professionalism, that is, what are the distinctive features of a profession, as opposed to other occupational forms (see Evetts and Svensson, 2010).

In recent times there has also been development in our understanding of the nature of 'work-based learning.' The relationship between experience, understanding, and knowledge has been a complex one that is very context dependent (McNamara et al., 2014). This has heightened awareness of the importance of creating an appropriate learning environment in the practicum setting as well as in the university.

In order to achieve an effective balance of the academic and the professional, it has come to be recognized in many – but not all – quarters that a crucial element in teacher education is the partnership between the university and the schools in which students are experiencing their field practice or practicum. In different settings such partnerships have been developed in different ways. Furlong et al. (2000) distinguished between complementary and cooperative partnerships. The latter approach draws schoolteachers and university tutors closer together in sharing own leadership of the whole program, whereas in the complementary approach the key element is that the school-based and university staff have very distinctive and different roles. In cooperative programs school staff will experience training for their roles alongside university staff and may take such roles as 'subject mentor' or 'professional tutor.'

The Continuum of Teacher Education

Thus far we have tended to focus on the first stages of teacher education, that of the preservice or initial phase. However one of the important themes to emerge from research over many years now has been to recognize that beginning teachers can only learn the beginnings of what they should be capable of at this stage. Such is the complexity and scope of learning required that the teachers' professional career is increasingly seen as the basis for lifelong learning. This is frequently seen as a series of phases or stages in teacher learning. Each phase or stage will require somewhat different approaches as well as focusing on different aspects of teachers' knowledge and skills.

Usually, it is suggested – and sometimes required – that following initial qualification, teachers should then enter a phase of 'induction,' typically the first 1 or 2 years of being employed as a teacher in a school. During this period, they may have a timetable commitment that is less than the full one expected of experienced teachers and they may be assigned a mentor who will work with them to help them build upon what they have learned in their initial program. The usual

emphasis here is to ensure that they are learning to understand the particular approaches adopted in their own school and are deepening their understanding of the particular learning needs of students within that setting.

Having established this grounding in their school, the next phase – typically 2–5 years of the career – is typified as the Early Professional Development phase. For some teachers this may be an opportunity to deepen their theoretical understanding of learning and teaching, perhaps through a Masters' program, and/or to broaden their curriculum knowledge, and/or to develop new roles in addition to their class or subject teaching, such as pastoral roles. Such development may often be associated with taking an increasingly inquiry-oriented approach to their teaching, effectively carrying out small-scale school-based research (Forde et al., 2006; Campbell et al., 2003).

Subsequent professional development, often referred to as Continuing Professional Development, may take a wide variety of forms and may be more dependent on how the teacher seeks to develop their careers. Do they wish to become a specialist teacher within a subject or with a particular age range or are they aspiring to take on formal leadership roles within the school perhaps as a middle leader and eventually as a senior leader? In most settings there are particular programs available for such leadership development.

Teaching Quality and Teacher Education – A Global Agenda?

International reviews of current trends in teacher education very clearly demonstrate how much 'convergence' is taking place, at least in certain aspects (e.g., Darling-Hammond and Lieberman, 2012; Townsend, 2011). We have seen the impact of international assessment surveys and we have seen how many national reviews have been commissioned to that have been tasked with seeking improvements to provision in teacher education. For example, from the Holmes Group in the United States in the 1980s (Holmes, 1986), more recent reviews in Austria during the first decade of this century, and a string of reports in the Republic of Ireland (Sahlberg et al., 2012), Northern Ireland, Scotland, and Wales (see Beauchamp et al., 2013).

As ideas of 'the knowledge economy' and the competitiveness associated with 'globalization' have developed, so has the politicization of education generally (Rizvi and Lingard, 2009), but not least in teacher education. Politicians across the world emphasize the importance of teachers and teaching (the UK Government White Paper of 2010 is actually called *The Importance of Teaching* (DfE, 2010)).

The emphasis on performance has moved from a focus on pupils/learners to include teachers as well. Education systems worldwide are imbued with an ethos of 'performativity' (Jeffrey and Troman, 2012), which has tended to lead toward making sure that all performance can be measured. This has been a factor in the creation of sets of standards to define teaching. These typically amount to a list of competences that teachers should be capable of demonstrating, according to the particular phase of their career. Sometimes these standards are based on explicit value commitments that refer to the purposes of education and to principles such as justice, equity, and integrity.

In some settings, such standards and competence statements are developed largely by members of the profession and/or their organizations. Elsewhere governments have taken it upon themselves to define these matters, which has tended to lead to a loss of goodwill and a lack of trust in the relationship between policymakers and teachers (Mahony and Hextall, 2000).

One of the major difficulties for teachers arising from these trends is the tendency for politicians to assume that what works in one setting will work in their own and so the idea that policies developed successfully in one context can be simply borrowed and introduced in another context and be as successful there has led to some difficulties.

It has to be said that the work of the McKinsey Corporation in sponsoring major international reviews has tended to contribute to this. Similarly the OECD in their country studies as well as in transnational surveys have tended to create an assumption that what works there will work here – even the titles of some of the reports tend to demonstrate this, e.g., *How the world's best-performing education systems come out on top*.

Research and Development in Teacher Education

If there has been a growing tendency for convergence in approaches to teacher education especially in the developed world, that is to some extent countered by some quite local initiatives which seek to offer creative and innovative alternatives to this 'homogenization' and it is these alternatives that this article will conclude by considering.

From the groundbreaking insights of John Dewey onward and often incorporating developments in learning theory, there has been a growing but eclectic body of practice that has sought to address some of the key challenges within teacher education very directly. These challenges include the nature of professional knowledge and the best sites for learning as a teacher, matters covered earlier in this article.

In a paper commissioned for an Inquiry into Research and Teacher Education by the British Educational Research Association and the Royal Society for the Arts, Burn and Mutton (2013) consider what is meant by evidence-informed clinical practice in teacher education. They identify a number of programs in the United Kingdom, the Netherlands, Finland, and the United States, which have sought to integrate theoretical and practical knowledge in the learning of beginning teachers. Like many other reviews they come to the conclusion that it is very difficult to demonstrate the increased efficacy of such approaches in terms of pupil outcomes, but they do provide a very strong rationale for such approaches offering the most fully developed approach to teacher professionalism that is available.

They cite the Oxford internship scheme as an early example of these approaches. This was developed in the 1980s explicitly as a partnership between a university department of education and about 30 secondary schools. The whole scheme was developed and managed by the partnership and continues to this day to provide a well-integrated model of professional learning. In the United States, they refer to Professional

Development Schools as an attempt to do something similar, as well as to the Teachers for a New Era (TNE) initiative, an attempt to develop clinical practice in 11 settings. TNE provided the inspiration for Scottish Teachers for a New Era at Aberdeen, which along with the Glasgow West initiative, are two Scottish schemes referred to.

Schemes such as these provide a basis for teachers to set out on their careers as inquiring professionals, so that they can subsequently develop a wider range of knowledge, understanding, and skills that enable them to enhance their roles as teachers, so that they may see teaching as an activist profession and may adopt an inquiry orientation as a stance to their work (Cochran-Smith and Lytle, 2009). The systematic deployment of research skills within the work of a teacher is not a new idea however – in the United States, John Dewey established a teaching laboratory at the University of Chicago in 1896 (Mayhew and Edwards, 2007) and in the United Kingdom, Lawrence Stenhouse (1975) developed the ideas of teacher as research and as curriculum developer.

Conclusion

In short there are a number of key points of contention about the purpose, function, and nature of teacher education. These debates have been a characteristic of teacher education since its inception as an societal institution. Many of the debates though have been heightened in recent times through the increased competitiveness between nations and the increased awareness of the significance of education in a globalized knowledge economy. To a large extent the underlying debate is about who should decide on policy and practice in teacher education. In democratic societies there is undoubtedly a role for elected representatives, but what is the role of 'consumers,' whether young people in schools or teachers in training, and what should be the roles of those with a direct involvement in the processes, that is the teacher educators, whether they are based in universities or in schools?

Teacher Expertise

Julian G Elliott, Durham University, Durham, UK

This article is a revision of the previous edition article by R. Bromme, volume 23, pp. 15459–15465, © 2001, Elsevier Ltd.

Abstract

In considering the key domains of teacher expertise this article differentiates between teachers' knowledge of (1) academic subject content, (2) teaching and learning, and (3) the interpersonal dynamics of classrooms. In relation to teaching and learning, pedagogical content knowledge and associated conceptual difficulties are identified and discussed. In considering pedagogical knowledge and teachers' interpersonal skills, the tacit nature of much expert knowledge is highlighted and the implications of this for teacher professional development are considered.

Introduction

In an age dominated by high stakes testing, it might seem possible to conceptualize the expert teacher as one whose students will perform at a higher level on key academic measures than would anticipated on the basis of their prior performance. Leaving aside the many rejoinders to this assertion, such as the important impact upon student performance of multiple factors other than the teacher, and claims that there is more to high-quality education than test scores, this position tells us little about the special characteristics of the expert teacher. The difficulty of articulating a clear set of behaviors as an indicator of teaching expertise has often led researchers to draw upon easily measurable criteria, such as years of teaching experience or professional group membership, when selecting samples for investigation (Palmer et al., 2005). However, while expertise is typically the product of prolonged experience, it is possible to have many years of teaching experience but fail to learn from this (Sternberg and Hedlund, 2002).

Expertise has been defined as, "… the characteristics, skills and knowledge that distinguish experts from novices and less experienced people" (Ericsson, 2006: p.3). It is unique to a particular domain of activity and its acquisition typically takes many thousands of hours of focused effort and practice (Ericsson, 1996). Following the redundancy of early approaches to the study of expertise that examined teachers' personality traits or the nature and frequency of isolated classroom actions, the advent of cognitive approaches in psychology resulted in an emphasis upon the complex processes that underpin decision making about specific actions (Berliner, 1994), in particular the ways in which experts structure knowledge qualitatively differently to novices. Studies indicated that experts can access such knowledge in a more efficient, fluid, and faster manner to help solve novel problems, aided by superior pattern recognition enabling an ability to 'read the situation,' and are more aware of what it is that they know and do not know (Glaser and Chi, 1988).

Compared with describing complex cognitive processes, outlining the key domains of a teacher's expertise is seemingly not a difficult task. Expert teachers must have a sound understanding of the subject that they teach (subject knowledge). However, it is clear that a sound academic grasp of a subject is, in itself, no guarantee that an individual will be a competent teacher. Academic material needs to be structured, represented, and presented in a way that can make it most accessible to students with very different needs and understandings (pedagogical knowledge). While *meta*-analytic studies have offered teachers valuable information about the effectiveness of different types of teaching activity (Hattie, 2011; Higgins et al., 2013), the ability to amend day-to-day learning experiences to the particular needs-specific groups of students involves highly complex expert knowledge. Finally, teachers need to be capable of sustaining sound professional and interpersonal relationships with adults (parents and colleagues) and children (Torff and Sessions, 2005; Malm and Löfgrer, 2006), particularly for the purposes of managing and orchestrating children's classroom behavior. Indeed, this is so fundamental to create an environment in which learning can take place, one may take issue with Ball et al.'s (2008: p. 404) assertion that, "… there may be nothing more foundational to teacher competency" than subject knowledge. Even disciplinary specialists with sound insights into the relationship between their subject areas and student learning processes, and an advanced capacity to provide meaningful learning activities, will struggle if they are unable to achieve an orderly, disciplined, and engaged classroom environment.

The Pedagogical Skills of the Expert Teacher

Within the domain of teaching and learning, it is possible to differentiate between general expertise that operates across disciplinary fields and that relating to the learning of specific subject matter (pedagogical content knowledge, PCK). The conception of PCK was developed by Shulman, (1986, 1987) as one of seven core areas of teacher knowledge:

> a) Content knowledge
> b) General pedagogical knowledge

> Shulman, 1987: p. 8

Shulman's conception concerned the 'special amalgam of content and pedagogy' (p.8) that was important for teaching a given subject or topic. His focus was upon the ways by which teachers transform subject matter knowledge to maximize student understandings. Knowledge of how this could be best achieved for a given topic in a given academic subject area in relation to the particular strengths and motivations of a given group of students, enables teachers to determine how best to structure the delivery of content, how to represent the material, and what forms of learning are best suited for the particular context. In this way, teacher expertise in relation to a given subject can be related to the number of representations and strategies they are able to generate, allied to their understanding of their students' particular learning needs.

In considering the forms of knowledge required to teach mathematics, Ball et al. (2008) built upon Shulman's conception to distinguish between two broad areas – subject matter knowledge and PCK. Subject matter knowledge consists of (1) disciplinary knowledge that is unrelated to teaching (common content knowledge), (2) that which is specific to the teaching process yet is clearly subject knowledge (for example, that which can provide understandings about particular student errors (specialized content knowledge)), and (3) knowledge of how specific topics fit within the wider span of the discipline (horizon knowledge). The value of horizon knowledge serves as a basis for claims that teachers of young children require advanced subject knowledge in key subject areas such as science and mathematics. Pedagogical content was similarly divided into three components, (1) knowledge of content and curriculum, (2) knowledge of content and students, and (3) knowledge of content and teaching. Sztajn et al. (2012) conceive of these in relation to student trajectories of learning whereby content and tasks are presented in ways that are closely aligned to students' increasingly sophisticated ways of thinking and understanding.

Currently there is no universally accepted understanding of the PCK term and, as is often the case with constructs in the social sciences that succeed in capturing the imagination, it has come to be used to describe a broader range of processes than was originally intended (for example, Ball et al.'s reformulation of Shulman's areas subsumes curriculum knowledge within PCK). There is a danger that, in some cases, the construct has broadened in scope to the point that it has become almost synonymous with teacher practices and beliefs in general (Hashweh, 2005). Van Driel and Berry (2010) note uncertainty as to whether PCK should be seen as wholly related to very specific topics or whether there are grounds for arguing that this can apply to broader disciplinary areas (for example, in relation to algebra or even the teaching of mathematics). They add that attempts to analyze PCK empirically may result in consideration of atomistic segments that may not adequately represent the complex and holistic nature of teaching.

A further difficulty of PCK, in relation to teacher expertise is that, despite much theorizing, there has been little research examining exactly how teachers actually transform subject knowledge in ways that reflect their views of their students' understandings (Van Driel and Berry, 2010). A related area of debate concerns the extent to which expert practices can be set out explicitly in ways that can inform the practice of others. Thus, Bausmith and Barry (2011) contend that PCK can be enhanced by the use of online videos of lessons taught by expert teachers. However, this does not sit easily with the emphasis upon teachers' developing understandings of their own particular contexts. As Van Driel and Berry (2012) point out, a topic such as 'force' may be taught differently, even to same-aged children, depending on the unique circumstances of a particular time and setting. The expert teacher not only modifies the approach they take according to such factors but can also make on the spot modifications in the light of changing circumstances.

The Interpersonal Skills of the Expert Teacher

A critical area of teacher expertise that is not highlighted in Shulman's seven categories concerns interpersonal dealings with students, parents, and colleagues. Creating and sustaining positive relationships with students is often perceived by teachers as the most difficult aspect of their work, particularly in schools with challenging circumstances (Johnson and Birkeland, 2003). Such a concern is particularly strong in many Western contexts where resistance to traditional authority figures has resulted in teachers feeling challenged both by students and parents (Maclure and Walker, 2000). Teachers often need to achieve disciplined environments by means of the exercise of their professional expertise rather than through the traditional sources of authority vested in them by the nation-state (Pace and Hemmings, 2007; Elliott and Tudge, 2007).

In relation to developing an orderly and engaged classroom environment, Elliott (2009) has argued that a fundamental skill of the expert teacher concerns their capacity to demonstrate authority. However, achieving this is often easier said than done and much of the relevant knowledge would seem to be tacit and context-bound. Despite this, it is possible to articulate some of the skills by which the teacher's expertise is communicated to their students.

It would seem that, when confronted by a challenging interpersonal problem, the expert teacher is more likely to identify a sound action from a range of possibilities. In an exploration of this, Elliott et al. (2011) presented novice and experienced teachers with a series of hypothetical school-related scenarios in which an interpersonal difficulty or challenge is presented. These scenarios, together with a list of possible responses, were derived from interviews with experienced teachers (see Stemler et al., 2006; Grigorenko et al., 2006). It was found that over time, novice teachers became more able to recognize undesirable responses as determined by their more experienced colleagues. However, there was little difference between the two groups in their capacity to identify 'good' responses. It appeared that the key learning for the novices centered upon avoiding poor choices. However, in considering the makeup of the samples it should be noted that experience should not be directly equated with expertise as tacit knowledge concerns the ability to learn from experience (Sternberg et al., 2000: Sternberg and Hedlund, 2002), a skill that would not appear to be the preserve of all teachers.

It is important to recognize that the expert teacher not only makes a wise choice about what steps to take in any given situation but should also carry these out with high levels of

skill. A decision for example, that one should confront a particular student presenting a problem in class requires the advanced interpersonal skill of achieving this satisfactorily. In addition, having knowledge of what might be the wisest step to take does not necessarily mean that the teacher will act in accordance with this. High levels of emotion, stress, or self-doubt may lead the teacher to respond in ways that they would not recommend if they were reflecting dispassionately and disinterestedly on possible courses of action. This may explain why there is little evidence that responses to teacher questionnaires actually predict the actual classroom behavior of teachers (Berliner, 2005).

A further difficulty with focusing upon reaction to challenging situations is that the expert teacher would appear to be not so much one who handles problems skillfully but, rather, one who prevents difficulties from emerging in the first place (Kounin, 1970). Those teachers who are presented with fewest challenges typically deploy a range of skills including an ability to: demonstrate an advanced awareness of everything taking place around them ('withitness'), orchestrate multiple events taking place at the same time ('overlapping'), operate clearly understood classroom routines, use their voice and body language in ways that signal authority and maintain student interest and alertness, (Van Tartwijk, 1993), and control spoken interactions in ways that ensure that the teacher is not overly responsive or subordinate to the child's agenda (Elliott and Place, 2012).

Teaching Expertise to Teachers and the Complexities of Tacit Knowledge

Given the vast reservoir of research that has been conducted on teacher skills, one might anticipate that it would be relatively straightforward to articulate a set of practices that is consonant with that of the expert teacher. Such a perspective is perhaps reflected by Bausmith and Barry's (2011) recommendation for the use of online videos of expert practice. Such a perspective has been criticized on the grounds that this reflects "… an outside-in, top-down, teacher-deficit model" (Anderson and Herr, 2011: p. 287) that has not been supported by research. To some extent this critique reflects a broader debate in education between those who advocate evidence-based approaches based upon models originating in the natural sciences, and others who advocate exploratory teacher action research involving reflection upon one's own professional practice, often in communion with colleagues (Feldman and Weiss, 2010).

A key difficulty for those seeking to help teachers develop classroom expertise is that the multiplicity of subtle factors, individual differences, and unique circumstances are such that attempts to offer relatively decontextualized guidance may lack sufficient meaningfulness, resonance, relevance, or value. Furthermore, unlike everyday routinized classroom practices and procedures (e.g., undertaking formal testing, managing student entry into the classroom, setting out equipment in the science laboratory) more complex professional understandings are often tacit and thus not easily made explicit as a set of guiding rules for action (Schön, 1983; Sternberg and Horvath, 1995).

Eraut (2000: p.133) has outlined a number of situations where tacit knowledge may be used and/or acquired in professional contexts:

1. Knowledge acquired by implicit learning of which the knower is unaware;
2. Knowledge constructed from the aggregation of episodes in long-term memory;
3. Knowledge inferred by observers to be capable of representation as implicit theories of action, personal constructs, schemas, etc.;
4. Knowledge which enables rapid, intuitive understanding or response;
5. Knowledge entailed in transferring knowledge from one situation to another; and
6. Knowledge embedded in taken-for-granted activities, perceptions and norms.

As this list demonstrates, rendering such knowledge formal and explicit is not an easily achievable undertaking. According to Sternberg and his colleagues (Sternberg and Horvath, 1995; Sternberg, 1997; Sternberg and Hedlund, 2002), and following the seminal work of Polanyi (1958), tacit knowledge is primarily acquired, not by direct instruction from others but, rather, from one's experience of operating within a given context. It typically takes the form of procedural knowledge that is concerned with how particular tasks are best undertaken in specific contexts. Furthermore, it is closely related to one's own goals and agendas and thus what might be understood as the most appropriate response to a given classroom incident will be influenced by the teacher's own beliefs and values.

Given these characteristics, it is hardly surprising that much of teachers' expert knowledge is not easily taught (Anderson, 1982) although, given that tacit knowledge is derived through experience, it seems that it can be facilitated by educational approaches that involve formal inputs, opportunities to experiment in practice, and the operation of teacher groups collectively thinking and reflecting upon their practice (Sternberg et al., 2000; Cianciolo et al., 2006; Van Driel and Berry, 2012).

In conclusion, while it is a truism that classroom learning will typically only be effective where the teacher seeks to exercise appropriate authority, demonstrates enthusiasm for the relevant academic material, and exhibits a strong desire to maximize the learning progress of the students, such dispositions are often insufficient. Additionally, it is the exercise of high-level professional expertise, not easily encapsulated by a set of straightforward practices that, while crucial, can prove elusive for some practitioners.

Teacher Leadership

Alma Harris, Institute of Education, University College, London, UK

Abstract

No modern concept has been more powerfully received by those concerned with school improvement and system reform than leadership. This article highlights the contemporary literature showing the importance of teacher leadership in generating and sustaining school and system improvement. Effective leadership, in the guise of the school principal, has long been identified with school success. The sheer volume of literature concerning school leadership is testament to its importance and ensures that it remains center stage in contemporary discussions about organizational change and development.

Current theorizing reinforces the view that leadership is not the preserve of the individual but is a social influence process whereby intentional influence is exerted by one person (or group) over other people or groups to structure the activities and relationships in a group or organization (Yukl, 1990). High-performing organizations are characterized by the fact that leadership is not identified with the qualities of an individual but rather is understood as behavior that facilitates collective action toward a common goal Hargreaves, Boyle and Harris, (2014). Such collective action resonates closely with the theory of 'distributed leadership' which draws particularly upon distributed cognition and activity theory (Harris, 2008, 2009, 2014). Both theories underscore how social context influences human interaction and learning and reinforce that leadership is a form of social influence that goes beyond individuals and implies collective agency (Ogawa and Bossert, 1995).

The seminal work by Spillane et al. (2001) suggests that distributed leadership is a way of understanding leadership as a practice that is shared and realized within extended groupings and networks (Spillane et al., 2001; Harris, 2004; Gronn, 2000; Hulpia et al., 2011). In this sense, leadership is best understood as *practice distributed over leaders, followers, and their situation* (Spillane et al., 2001, p. 13). This distributed view of leadership *incorporates the activities of multiple groups of individuals in a school guiding and mobilizing staff in the process of instructional change* (Spillane et al., 2001, p. 13). Teacher agency, instruction, and collaboration are implicit within a model of distributed leadership. Although the distributed leadership literature has not explicitly acknowledged the idea of 'teacher leadership,' the same theoretical and conceptual terrain is clearly shared (Harris and Muijs, 2004).

Teacher Leadership

There is a substantial body of literature that focuses exclusively on the nature, form, and impact of teacher leadership (see York-Barr and Duke, 2004; Harris and Muijs, 2004). From this evidence base it is immediately evident that there are overlapping and competing definitions of the concept. York-Barr and Duke (2004, p. 260) note "in writing about teacher leadership, many authors readily assert its importance but usually fail to define it." Predictably, the lack of a consistent and precise definition in the literature has resulted in teacher leadership being loosely associated with a wide range of activities, roles, and behaviors. It has also meant that teacher leadership has become a convenient 'catch-all phrase' for diverse forms of teacher activity, engagement, and collaboration (York-Barr and Duke, 2004, p. 260).

To understand the variation of interpretation, it is important to look at the evolution of teacher leadership. The first phase of teacher leadership equates with recognition of the importance of the formal leadership roles that teachers undertake (e.g., department heads, pastoral leaders). In the second phase, teacher leadership became associated with the instructional expertise of teachers and their potential to develop the professional expertise of others. In the third phase, teacher leaders are viewed as central to the process of generating organizational development and change through their ability to influence others and their contribution to capacity building.

Katzenmeyer and Moller (2001, p. 17) define teacher leaders as teachers, who are leaders within and beyond the classroom, who identify with and contribute to a community of teacher learners and leaders, and influence others toward improved educational practice. Boles and Troen (1994, p. 11) characterize teacher leadership as a form of collective leadership in which teachers develop expertise by working collaboratively. Harris and Muijs (2004) suggest that there are four discernible dimensions of the teacher leadership role. The first dimension concerns the way in which teachers work with and across school boundaries and structures to establish social linkages within the community. This *brokering* role remains a central responsibility for the teacher as leader as it ensures that links within and across schools are in place and that opportunities for meaningful development among teachers are maximized. A second dimension of the teacher leader role focuses upon *participative* leadership where teachers work collegially with other teachers to encourage the examination of instructional practices.

A third dimension of teacher leadership is the *mediating role*. This suggests that teacher leaders are important sources of instructional expertise and information because they demonstrate high levels of instructional expertise. The final and possibly the most important dimension of the teacher leadership role, is that of *instructional leader*, i.e., forging close relationships with individual teachers so that reciprocal learning takes place.

In summary, there are a number of important things to highlight about teacher leadership from the literature. First,

 http://dx.doi.org/10.1016/B978-0-08-097086-8.92135-4

teacher leadership is associated with the creation of *collegial norms* among teachers that can contribute directly to school effectiveness, improvement, and development. Second, teacher leadership equates with giving teachers *opportunities to lead* which can have a positive influence upon individual self-efficacy and motivation. Third, at its most practical level, teacher leadership means that teachers are *working as instructional leaders* influencing curriculum, teaching, and the professional practice of others.

The next section considers the evidence about the impact of teacher leadership upon organizational and individual outcomes. It looks at the impact of teacher leadership at the school, teacher, and student level.

The Impact of Teacher Leadership: The School Level

The findings about the impact of teacher leadership at the school level are rather variable. Some studies indicate strong school level effects (Griffin, 1995) while others indicate the negligible influence of teacher leadership upon the school level. The greatest support for a relationship between teacher leadership and organizational change can be located within the school effectiveness, improvement, and reform literature. Here evidence suggests that generating teacher leadership, with its combination of increased teacher collaboration and increased responsibility, has positive effects on transforming schools and systems (Fullan, 2011; Harris, 2011; Harris and Jones, 2011).

Research has also reinforced that an organization's ability to improve and sustain improvement largely depends upon its ability to foster and nurture professional learning communities or 'communities of practice' (Morrissey, 2000; Holden, 2002). Linked to the idea of communities of practice, school improvement advocates have suggested that schools should operate as a professional learning community. Hargreaves (2000, p. 3) suggests "professional learning communities lead to strong and measurable improvements in students' learning. Instead of bringing about 'quick fixes' or superficial change, they create and support sustainable improvements that last over time because they build professional skill and the capacity to keep the school progressing." This idea of professional learning communities implies a commitment to teachers sharing learning and working collaboratively. It also embraces the notion of teacher leadership as it is assumed that teachers will be the main catalysts for change and development within a professional learning community (Louis and Stoll, 2007; Harris and Jones, 2011).

In summary, the literature confirms the positive effects of focused teacher collaboration upon organizational development and change. Where teacher leadership manifests itself in the development of trusting and collaborative relationships with colleagues, there is evidence that it does positively influence school culture and can generate the conditions where there are positive instructional and organizational outcomes.

The Impact of Teacher Leadership: The Teacher Level

By far the most discernible and powerful effect of teacher leadership is on the teacher leaders themselves. Research findings suggest that empowering teachers to lead enhances self-esteem and work satisfaction, which in turn leads to higher levels of performance and potentially much better outcomes for learners. Lieberman et al. (2000) reported that the teachers felt the experience of leading had improved their confidence in their own abilities, and had taught them to motivate, lead, and encourage other adults. Similarly, O'Connor and Boles (1992) reported improved self-confidence, increased knowledge, and an improved attitude to teaching among teachers who had been designated as leaders.

As highlighted earlier, the nature and quality of leadership within schools has been found to be an important condition for maximizing school effectiveness and improvement. Yet the relationship between teacher leadership and teacher effectiveness is generally implied in the literature rather than proven. The evidence shows that in schools where achievement is high, senior leaders tend to be more confident in allowing teachers to take on leadership roles. As one US study showed, improving student outcomes appeared as a condition for, rather than a result of, teacher leadership (Dickerson, 1992).

Teacher leadership has also reported to have effects on teacher practices at the classroom level. Smylie's (1994) review of redesignated teacher work and its effects on classroom practice drew two primary conclusions. First, that change in classroom practices was more likely to occur among those teachers whose work was redesigned, i.e., the teacher leaders and second, changes in classroom practice were more likely to occur when initiatives were collective, as opposed to individual.

In summary, the findings from the available studies suggest that teacher leadership is positively related to changes in teachers' classroom practice and their instructional effectiveness.

The Impact of Teacher Leadership: The Student Level

York-Barr and Duke (2004) found only five studies that directly examined the impact of teacher leadership on students. The first conducted by Ryan (1999) studied three schools where teacher leaders were found to be having a positive effect on students because they influenced the instructional practices of colleagues and were involved in school level decision-making. The second by Louis and Marks (1998) did not discern a direct relationship between teacher empowerment and student learning but strongly supported the argument that empowerment did positively influence teachers' efforts to improve instruction. The third by Taylor and Bogotch (1994) found no significant difference in terms of student attendance, achievement, or behavior between schools with high degrees of teacher participation in decision-making as opposed to schools with low degrees of teacher participation in decision-making.

The other two studies conducted by Leithwood and Jantzi (1999, 2000) explored the effects of school and teacher leadership on students' engagement with school. This study reported no statistically significant relationship between teacher leadership and student engagement. However it did conclude that teacher leadership outweighs principal leadership effects before taking into account the moderating effects of family educational culture.

In contrast, other studies have shown a more positive relationship between teacher leadership and student learning outcomes. Research by Silns and Mulford (2002) concluded

that student outcomes are more likely to improve where leadership sources are distributed throughout the school community and where teachers are empowered to lead. Similarly, a study of 86 US middle schools found that both teacher professionalism and collegial leadership were positively related to improved student outcomes (Hoy et al., 1998). Other work by Eddy- Spicer (2011) and Lemlech and Hertzog (1998) has suggested that encouraging teachers to take on leadership roles positively affects self-efficacy and behavior which subsequently influences student learning outcomes. Harris and Muijs (2004) found an indirect relationship between teacher involvement in decision-making and improved student outcomes.

In summary, the direct link between teacher leadership and improved learner outcomes is far from clear or established. The literature confirms that where instructional improvement is at the heart of the work of teacher leaders, there is a much greater chance of a positive impact upon student learning outcomes.

Conclusion

Within the literature there is substantial evidence to suggest that teacher leadership can have a positive impact upon teachers' self-efficacy, instructional knowledge, and professional relationships. The evidence also supports the positive benefits of teacher leadership upon the practice of other teachers and endorses a strong relationship between teacher leadership, in the form of greater involvement in decision-making, with positive organizational development. For those working toward school and system reform the implication is clear; if properly constructed and appropriately deployed, teacher leadership can be a powerful way to build the collective capacity so that school and system transformation is secured and sustained.

Teacher Motivation

Helen MG Watt and Paul W Richardson, Faculty of Education, Monash University, Melbourne, Victoria, Australia

Abstract

Motivational theories were developed in relation to students; over the last decade, researchers have turned their attention also to teachers. We overview each of three major motivation theories (expectancy-value, achievement goal, and self-determination) that have thus far been reinterpreted in relation to teachers, involving the adaptation of constructs and processes initially designed to understand students' motivations. Empirical findings pertaining to teachers' motivations are summarized, cultural differences contrasted, and methodological issues raised. We conclude with implications and suggestions for future research in the field.

Teacher Motivation: Theoretical and Empirical Developments

The last decade has seen something of a 'Zeitgeist' of research in the burgeoning field of teacher motivation. Theoretical developments have been concentrated to address pressing questions concerning teachers' career entry and commitment, professional effort exertion and instructional behaviors, and professional growth and personal well-being. Although the study of teacher motivation is not in itself new, until recently researchers had not drawn upon the motivation literature in an intensive or systematic way to develop theoretically grounded and psychometrically strong models. In the last decade, theories, constructs, and concepts from the well-established student motivation literature have been extrapolated to the study of teacher motivation. Transposing theoretical concepts to the previously neglected domain of teaching has required the adaptation of theories that were not originally developed to apply to teachers.

Motivation researchers have asked, first, what kinds of motivations are relevant for teachers; second, whether and how we can measure them; and third, whether and how they matter. Empirical findings have begun to demonstrate the importance of teachers' motivations for both teachers and their students. In this endeavor, the choice of theoretical lens has depended upon the outcomes under investigation. We began our program of research drawing upon expectancy-value theory (EVT) because we were interested in why individuals choose to pursue teaching as a career and consequences for their professional engagement, teaching style, and personal well-being (Watt and Richardson, 2007a, 2008). In other lines of research, achievement goal theory (AGT) has focused on how teachers strive to feel successful and how success is conceived in their daily work because the classroom is an achievement arena for teachers as well as students (Butler, 2007). Self-determination theory (SDT), which is more generally concerned with human growth and functioning, has explored teachers' controlled versus autonomous motivations, consequences for teachers' quality instructional behaviors versus burnout, and consequences for the quality of their students' motivation (see Fernet et al., 2012; Pelletier et al., 2002; Roth, 2014).

With the exception of self-efficacy theory, motivational theories have only recently begun to be adapted and applied to the study of teacher motivation. Teacher self-efficacy refers to the degree to which teachers feel efficacious to enact certain professional outcomes such as deploying effective instructional strategies, classroom management, and engaging students (Tschannen-Moran and Woolfolk Hoy, 2001). Studies of teachers' self-efficacy have shown that higher self-efficacy predicts many positive attitudes and behaviors for teachers and students, including innovative teaching strategies, task persistence, resilience and well-being, and student motivation and achievement (see Klassen et al., 2011; Tschannen-Moran et al., 1998).

In this article, we begin with an overview of each of the three major motivation theories influencing research on teachers, involving the adaptation of constructs and processes initially designed to understand students' motivations. We next review empirical findings pertaining to teachers' motivations, paying particular attention to EVT within which our work has concentrated. We conclude with implications and suggestions for future research in the field.

Theories of Teacher Motivation

Expectancy-Value Theory

The Eccles et al. model of EVT (see Eccles, 2009) proposes that one's educational, vocational, and other achievement-related choices are shaped, on the one hand, by one's ability beliefs and expectancies for success, and on the other, by the value attached to the task. The values component is comprised of how much a person enjoys the task (intrinsic value), whether it is seen to be useful (utility value), whether it is seen as being important for achieving a person's goals (attainment value), and how costly it will be to succeed in relation to what an individual must forego in undertaking a task (opportunity cost), entailing negative effects such as financial loss, psychological experiences (e.g., anxiety, stress), time commitment, or effort expenditure (see Perez et al., 2014).

Originally developed to examine gendered patterns of enrollment in senior high mathematics (Eccles (Parsons) et al., 1983), the model has been applied to the selection of various different types of careers (e.g., Watt et al., 2012b). Drawing on this work, the Factors Influencing Teaching Choice (FIT-Choice;

 http://dx.doi.org/10.1016/B978-0-08-097086-8.26082-0

www.fitchoice.org) framework was advanced as a coherent theoretical model to propel systematic enquiry into key motivations for choosing teaching as a career (**Figure 1**; see Richardson and Watt, 2006, 2010; Watt and Richardson, 2007a, 2008).

What Motivates People to Choose a Teaching Career?

Researchers from widely different disciplinary approaches and using diverse methodologies have explored what motivates people to choose teaching as a career and, more specifically, why they sign up to be early childhood, elementary, or secondary school teachers of particular subjects. Given that teachers constitute a large, heterogeneous workforce, substantially funded from the public purse, it is not surprising that policymakers have turned their attention to what attracts people to teaching as a career, especially when faced with recruitment problems, shortages of specialist teachers, early attrition from the career, and more recently, insistent pressure to improve the quality of the teaching workforce.

Motivations for choosing teaching as a career identified in the 1960s and 1970s, particularly in large-scale American studies, focused on the desire for social mobility, the influence of parents and extended family, a desire to work with young children and adolescents, to work in a people-oriented profession, and job-related benefits such as security, pensions, and holidays (National Education Association, 1976). Even though there has been a steady stream of studies over the last five decades examining teaching choice and teachers' work and lives (e.g., Connell, 1985; Day et al., 2007; Huberman, 1993; Lortie, 2002), the approaches have been diverse, making comparisons of findings across studies difficult.

Until the last decade, the US accounted for the largest number of studies of teachers' career choice motivations. These mostly relied on questionnaires designed by researchers, including factors that frequently bore little relationship to one another, as well as numerous qualitative studies, precluding comparisons across samples or settings. Moreover, there was little agreement among researchers concerning underpinning theoretical frameworks or measures and a reliance on single-timepoint studies of participants who had self-selected into teaching. In reviewing this corpus of research up until the early 1990s, Brookhart and Freeman in their seminal analysis summarized, "altruistic, service-oriented goals and other intrinsic motivations are the source of the primary reasons entering teacher candidates report for why they chose teaching as a career" (1992: 46).

Since then, an OECD review of studies (2005), based on studies from France, Australia, Belgium (French Community), Canada (Québec), the Netherlands, the Slovak Republic, and the UK, reported that the most common motivations for teaching are the desire to work with youth, potential for intellectual fulfillment, and making a social contribution. The desire to work with children and adolescents has been identified as central in many studies (e.g., Fox, 1961; Joseph and Green, 1986; Kyriacou and Coulthard, 2000; Lortie, 2002; Tudhope, 1944), whereas extrinsic motives such as salary, job security, and career status have been more important in different sociocultural contexts such as Brunei (Yong, 1995), Zimbabwe (Chivore, 1988), Cameroon (Abangma, 1981), the Caribbean (Brown, 1992), Jamaica (Bastick, 1999), and Turkey (Kılınç et al., 2012). The absence of an agreed theoretical and analytical framework, however, has meant that researchers vary

Figure 1 FIT-Choice theoretical model.

on what constitutes intrinsic, altruistic, extrinsic, or other motivations. For example, the desire to work with children has at times been referred to as an intrinsic (e.g., Young, 1995) and at other times as an altruistic motivation (e.g., Yong, 1995).

EVT provided a fruitful and coherent framework to guide our research concerning the motivation to choose a teaching career. We mapped motivations previously identified as influential in the teacher education literature to constructs in the expectancy-value framework, which allowed us to locate previously identified motivations within an integrative and comprehensive model, which additionally suggested other important motivations. Our FIT-Choice program of research began at its outset with the development of the FIT-Choice scale.

The FIT-Choice scale is psychometrically sound and yields reliable findings across settings (Watt and Richardson, 2007a, 2012; Watt et al., 2012a). It taps the altruistic-type motivations, often emphasized in the Western teacher education literature, such as to shape the future of children/adolescents, enhance social equity, make a social contribution, and work with children/adolescents (e.g., Book and Freeman, 1986; Brown, 1992; Lortie, 2002; Moran et al., 2001; Serow and Forrest, 1994), and ability-related beliefs that predominate in the career choice literature (Lent et al., 1993). The scale also elicits individuals' personally utilitarian motivations that tap quality of life issues such as job security, time for family, and job transferability; intrinsic motivations; social influences stemming from friends, family, or work colleagues who promote the idea that one is suited to be a teacher; positive prior teaching and learning experiences; and the negative motivation of having chosen teaching as a 'fallback' career (see Book et al., 1985; Haubrich, 1960; Robertson et al., 1983). The FIT-Choice framework also assesses perceptions of the demands (heavy workload, emotional demands, hard work), the rewards of teaching as a career (salary and social status), and career choice satisfaction. An imbalance between demands and rewards is conceptualized as a cost.

The FIT-Choice measurement platform allows for the identification of which motivations and task beliefs are more and less important for choosing teaching as a career. It also permits comparisons of the measured factors across settings, including Australia (Richardson and Watt, 2006), the United States (Lin et al., 2012; Watt et al., 2012a), Norway (Watt, et al., 2012a), Croatia (Jugović et al., 2012), China (Lin et al., 2012), Turkey (Kılınç et al., 2012), Germany (König and Rothland, 2012; Watt et al., 2012a), and Switzerland (Berger and D'Ascoli, 2012).

In general, teachers' motivations were more similar than they were different, although further studies in different sociocultural contexts are needed. Fallback career motivations were uniformly low, except in China and Turkey, likely reflecting the availability of career and work within those labor markets. Ability and intrinsic motivations were rated highly among all but the samples from China and Turkey, in which collectivist cultures career choices may be less based on individual interests and abilities, or more basic needs such as job security may have primacy in a newly industrialized country, such as Turkey, in which that sample indeed scored highest. Altruistic-type values (i.e., social utility values) were high in general, but notably lowest in the Chinese sample and in the middle for the German sample. The expectation of making a contribution to society may be taken more for granted in collectivistic Chinese culture, and the tracked school system in Germany could mean future teachers perceive lower agency to achieve social equity outcomes and youth opportunities through educational structures. Personal utility values were strikingly similar and rated moderately across samples, presumably reflecting basic needs in contemporary society, although, as mentioned, the Turkish sample rated job security somewhat higher.

In general, future teachers believed teaching is a highly demanding career (including heavy workload, emotional demand, and hard work), with low rewards in terms of salary and social status. The Chinese and especially the Turkish sample rated the demands of teaching substantially lower, possibly due to the collectivist approach to teacher development and group accountability in the Chinese sample, and the relative demandingness of alternative available work in the developing Turkish context. Perceptions of higher salary in the German setting reflected objective context differences. Values about teaching as a socially responsible and morally worthwhile career starkly contrast with fallback and personally utilitarian values, or beliefs that monetary rewards and status are important career outcomes.

EVT further posits that expectancies and values predict domain-specific achievement behaviors such as performance, efforts, and persistence. Yet, little is known about the long-term effects of initial teaching motivations. Can they have lasting effects on professional engagement and even on beginning teachers' subsequent teaching styles? Results from our longitudinal study highlight an enduring effect of initial motivations for choosing teaching, which, in turn, predict professional engagement and teaching styles up to 8 years later. We examined the extent to which initial motivations for teaching influenced professional engagement and career development aspirations (PECDA; Watt and Richardson, 2008) and self-reported teaching style (TSS; Watt and Richardson, 2007b), using longitudinal Australian FIT-Choice data spanning entry to teacher education (Time 1), exit from teacher education (Time 2), and after up 8 years of teaching experience (Time 3). Intrinsic and ability motivations to teach at Time 1 predicted Time 3 positive-reported teaching behaviors, as did social utility values through their influence on whether participants planned to remain in the profession at Time 2. Conversely, fallback career motivations predicted lowered PECDA and reduced positive teaching behaviors during early career. Social influences, such as being persuaded by family, friends, or others to become a teacher, predicted negative-reported teaching practices (see Richardson and Watt, 2014).

The most adaptive motivations for choosing teaching as a career were thus positive ability self-beliefs, intrinsic enjoyment of teaching, wanting to work with youth in order to help them shape their futures, and wanting to make a social contribution by enhancing social equity (social utility values). Problematic motivations were entering teaching as a fallback career and due to external social influences, both of which predicted later teaching negativity (including responding negatively or angrily to students' mistakes, use

of sarcasm, or deliberate embarrassment) (Richardson and Watt, 2014). We interpret the negative consequences from entering teaching due to external social influence in terms of SDT in that choosing a teaching career based on persuasion from others suggests a 'controlled' rather than an 'autonomous' motivation. These results have implications for teacher recruitment efforts; the negative effect of social influences needs to be carefully considered when persuading individuals into the teaching profession.

A comprehensive research strategy on teacher motivation needs to address several core issues: Why choose the career of being a teacher?; Why do people stay in the job, burnout, or leave?; How do motivations intersect with sociocultural factors to impact teachers' professional development and personal well-being?; and What types of profiles are evident in teachers' career trajectories? Such questions require following the same individuals over an extended period of time to address critical issues in the current climate of teacher shortages and concern regarding teacher quality with implications for policymakers, employers, and teacher educators. Longitudinal data allow the real and necessary opportunity to explore and test how processes unfold over time to produce outcomes. There are few high-quality longitudinal studies to address these questions.

Achievement Goal Theory

AGT originally distinguished a task (or mastery) from an ego (or performance) goal orientation (Dweck and Elliott, 1983; Nicholls, 1989). Since then, the trichotomous goal framework was proposed (Elliot and Church, 1997; Elliot and Harackiewicz, 1996; Nicholls, 1989), which distinguished *performance-approach* from *performance-avoidance* goals. Individuals who hold a performance-approach goal are motivated to demonstrate their abilities relative to others, in contrast to those who hold a performance-avoidance goal and are motivated to avoid demonstrating their relative lack of ability. A parallel distinction was subsequently proposed for mastery goals in the 2×2 achievement goal framework (see Bong, 2009; Elliot and McGregor, 2001; Harackiewicz et al., 2002), which introduced a mastery avoidance goal, defined as a focus to avoid misunderstanding, not learning, or not mastering a task. The two approach goal orientations predict positive outcomes, with mastery approach being the most positive. In contrast, performance-avoidance goals predict maladaptive outcomes, particularly when self-beliefs of competence are low (Law et al., 2012).

What Goals Are Teachers Motivated to Achieve?

Prompted by the notion that the classroom may function as an achievement arena for teachers as well as for students, Butler (2007) began to explore teachers' goals. Her program of research began with the development of the Goal Orientations for Teaching scale (2007), a self-report measure first used in a study with Israeli teachers and subsequently with samples of preservice and practising teachers in Germany (Dickhäuser et al., 2007; Retelsdorf et al., 2010). The scale identified four factors that reflect a mastery orientation (acquiring and developing professional competence), an ability-approach orientation (demonstrating superior teaching ability), an ability-avoidance orientation (avoiding displaying inferior teaching ability), and a work-avoidance orientation (to get through the day with as little effort as possible). Based on the logic that teaching is an inherently interpersonal activity, Butler (2012) subsequently identified a distinct new class of goal – relational goals – that describes teacher strivings to create caring relationships with their students.

Important links exist between teachers' achievement goals, patterns of communication and behavior in the classroom, and students' resultant learning and achievement outcomes (Butler, 2007, 2014; Butler and Shibaz, 2008). Similar to patterns of findings concerning students' achievement goals, teachers' mastery goals were associated with positive outcomes, including adaptive coping and engagement, mastery-oriented instruction, and their students' engagement. Performance-avoidance goals (to avoid the demonstration of poor teaching ability) predicted clear negative outcomes, including defensive avoidance of help, self-handicapping, burnout, career dissatisfaction, and surface approaches to instruction involving more competitive classroom climates. Patterns for performance-approach goals (to prove ability) were less clear-cut. Findings concerning the newly identified class of relational goals showed these teachers provided greater socioemotional support to students and cognitively stimulating instruction (see Butler, 2012, 2014). Similarly, Shim et al. (2013) found that teachers' achievement goals were associated with the classroom environments they created in the Midwestern United States: Mastery goals for teaching predicted the creation of classroom mastery environments and performance-approach goals predicted a classroom performance focus.

Using the Shim et al. (2013) data set, Cho and Shim (2013) examined the association of the work environment with teachers' goals for their teaching: Teachers who perceived a mastery-oriented school environment adopted mastery goals for teaching, whereas teachers working in school environments that they perceived as performance-oriented were more likely to adopt performance-approach goals for teaching. Interestingly, those teachers with the highest levels of self-efficacy endorsed both mastery and performance-approach goals and maintained high mastery goals for their teaching even when the school encouraged performance goals; teachers with lower self-efficacy conformed to the school goal environment. In another US study, highly performance-oriented school environments were associated with teachers' adoption of performance-approach goals for teaching, reduced motivations, and lowered sense of community (Ciani et al., 2008). These studies highlight the importance of school cultures and their impact on teachers' own goals for teaching.

Teachers' ideographic goals have been explored in order to determine whether additional goals should be assessed. Hagger and Malmberg (2011) identified 13 goals among a sample of preservice teachers, reflecting six self-related (self, teacher engagement, behavior management, teacher education course, collegial relationships, career), four task-related (teaching strategies, subject/curriculum knowledge, planning and organization, taking account of individual differences), and three student impact goals (student engagement, relationship with students, teacher impact). Goal contents were found to predict preservice teachers' concerns, and both self-esteem and depression.

In another study among preservice teachers, drawing upon Ford and Nichols' (1987) Taxonomy of Human Goals, Mansfield et al. (2012) identified within-person (affective and cognitive) and person–environment (social relationship and task) goals. It is noteworthy that the goals in these two studies encompassed a broad range of professional activities, aspirations, and conceptions of beginning teachers. Further research could explore ideographic goals among practising teachers, the role of teaching experience in goal contents and differentiation, and other correlates of teachers' goal contents for themselves and their students.

Self-Determination Theory

SDT (Deci and Ryan, 1985; Ryan and Deci, 2000) posits that fulfillment of three basic innate, human psychological needs (*autonomy*, *competence*, and *relatedness*) is necessary for optimal human functioning. When support for these needs is available, people will be intrinsically motivated to undertake tasks for their own sake because they are interesting, enjoyable, and inherently rewarding. Under these conditions, people are autonomously motivated. By contrast, when these psychological needs are unsupported or thwarted, wellness and growth will be negatively affected. In studies of student learning, autonomy relates to choice, competence refers to feeling efficacious during learning tasks, and relatedness refers to feeling connected to the teacher and class. The satisfaction of these needs is a necessary condition for learning.

SDT offers a potentially rich perspective on how individuals develop and internalize their motivations. *External regulation* is the least self-determined, least autonomous form of motivation, and located at the opposite end of the continuum from *intrinsic regulation*. Between the extremes of extrinsic and intrinsic motivation, differentiated levels of regulation occur; *introjected regulation* refers to forms of regulation that are taken in by the individual and provide for self-imposed pressures or 'should,' whereas *identified regulation* is experienced when individuals identify with the worth of an activity or behavior and engage in it accordingly (Ryan and Deci, 2000). Thus, intrinsic and extrinsic motivations are located at two ends of an internalization continuum with movement along that continuum being signaled by structural changes that progressively transform externally based regulations into a more internal personal regulatory system (cf Grolnick et al., 1997). Movement along this continuum means that an individual's experience of regulation is progressively more autonomous, integrated, and self-determined with initiated behaviors performed out of choice, simultaneously meeting an individual's innate need for a sense of competence, autonomy, and relatedness.

The key differentiation drawn by SDT theorists is between autonomous (or self-determined) and controlled motivations. Autonomous motivation involves volition and choice, and controlled motivation involves an external or internal sense of compulsion (Assor et al., 2004; Grolnick et al., 1997). It is possible that initially autonomous motivations could become controlled motivations, for example, when an initial decision (such as to become a teacher) is autonomous, but then actually doing the work entails a sense of compulsion or external responsibility. A large literature has examined predictors of students' autonomous motivation and benefits for their engagement and well-being (see Ryan and Deci, 2009).

What Are the Consequences of Teachers' Self-Determined Motivations?

The research based in SDT on teachers is quite scarce (see Roth, 2014). When teachers perform their job for the intrinsic value of working with and achieving positive outcomes for their students, they are said to be autonomously motivated. Yet, when teachers are externally regulated by invasive policies, curriculum requirements, principal supervision, and administrative practices, the theory posits that they experience low levels of choice in initiating behavior and a reduced sense of competence and autonomy (Fernet et al., 2012). In studies of teachers, autonomous motivations, such as to let children feel that teachers care about them or being in touch with children and adolescents (Roth et al., 2007), are associated with perceived accomplishment, teaching self-efficacy, autonomy-supportive teaching practices, and reduced burnout. Autonomous teacher motivation has additionally been found to be associated with autonomy-supportive teaching practices that furnish choice and relevance to students (Fernet et al., 2012; Pelletier et al., 2002; Roth et al., 2007; Taylor and Ntoumanis, 2007; Taylor et al., 2008).

Outlook and Future Directions

Over the last decade or so, there has been an intensification of interest in teacher motivation by researchers who have developed programs of research founded upon robust psychological theories of motivation to address questions such as those which structure our continuing FIT-Choice program: What motivates people to choose teaching as a career? How are teacher motivations constituted? Are teacher motivations stable or malleable, and to what degree? Do initial teacher motivations matter in the longer term and how? Why do many early-career teachers leave the profession? What are the factors that support teachers' confidence, motivation, and commitment to be an effective teacher over many years? What factors undermine teachers' motivation and commitment? Do teacher motivations relate to positive student learning outcomes? How are teacher motivations influenced by different contextual factors at the state, district, school, and classroom levels? How do teacher motivations differ across cultural and social contexts? Are there 'core' teacher motivations that do not vary substantially across social and cultural contexts?

Comparatively little attention has been given to teacher motivations at different points along a teacher's working life. A stage-based model of teachers' career development proposed by Huberman (1993) suggests that teacher motivations are not stable. While this model has heuristic appeal and has been reaffirmed in a cross-sectional study by Day et al. (2007), the question of whether teacher motivations are stable, change over time, respond to different contexts, or are malleable remains to be empirically tested using longitudinal designs. We are presently lacking a coherent developmental theoretical approach to the study of teachers' motivations throughout their career. In this pursuit, we may not wish

to keep measuring the same motivational factors over time; it may be that we need to invoke different theories as we seek to understand different developmental stages across the career life span. For example, EVT may be most relevant to the choice of teaching as a career, AGT for teachers' daily practices, and SDT to the promotion of self-determined teaching behaviors. It will be important to examine the motivations that sustain versus deter teachers in the profession, which may not be simply opposite sides of the same coin.

We expect that different kinds of school contexts will afford the realization or not of teachers' motivations, which, if left unfulfilled, could create a double-edged sword and lead to burnout and disappointment (see de Jesus and Lens, 2005). Teachers who are motivated to work with youth and enhance social equity, for example, find themselves frustrated and dispirited when their time is taken up by administrative and accountability work, which takes them away from what they believe are their core responsibilities. This creates a disjuncture between why teachers want to teach and the work they are required to spend their time doing. People who became teachers because they want to work with children and adolescents become less satisfied with their work if they have little time to engage in relational work on a daily basis. In this way, the same motivations can be a driving force for good or ill, dependent on the degree of match between a teacher and the teaching environment.

In determining which motivations are adaptive versus maladaptive, it is essential to consider what outcomes are being predicted and within what contexts. The decision of which outcomes ought to serve as outcome criteria in this endeavor is nontrivial before implications for policy and practice can be clarified. Stable and nonmalleable factors (for example, temperament) may be best considered at selection into teacher education, whereas changeable or malleable factors should be addressed during teacher education and early career induction. There is an urgent need for reliable, large-scale, long-term, cross-cultural data, incorporating extensive quantitative measures alongside targeted rich qualitative components, to examine the what and the why of teacher motivations and development over time and across settings.

Researchers are themselves experiencing something of a revolution as new methodological possibilities become available. There has been a reliance on self-report surveys in much of the motivational research literature, and it is increasingly recognized that multiple data sources and informants are required to understand the complexity of the antecedents, development, and outcomes of teacher motivations. Large-scale study designs that embrace and frame self-report qualitative interviews, and experience sampling methods that capture the dynamics of motivational systems, open up possibilities for illuminating processes at the individual and group level for different types of teachers. Structured observations (e.g., Pianta et al., 2008) can also provide more objective measurements concerning the expressed motivational elements of teachers' instruction and students' learning; student surveys provide complementary perspectives to, and outcomes from, teacher motivation. Teacher motivation research is increasingly drawing upon and informing other relevant domains of educational psychology, including self-efficacy, beliefs, future-time perspective, emotions, coping, responsibility, personality, and unconscious motivations (see Richardson et al., 2014), all of which link to the same outcomes with which teacher motivation researchers are ultimately concerned: teaching quality and student outcomes.

Teacher Stress and Burnout: Methodological Perspectives

Chris Kyriacou, University of York, York, UK

© 2015 Elsevier Ltd. All rights reserved.

This article is a revision of the previous edition article by R.S. Guglielmi, volume 23, pp. 15465–15468, © 2001, Elsevier Ltd.

Abstract

Teacher stress can be defined as the teacher's experience of negative emotions such as anxiety, frustration, tension, anger, or depression, in response to the demands and pressures they face in their work as a teacher. Teaching in schools is widely recognized as being one of the high-stress occupations. Our understanding of the nature of teacher stress and the processes involved provides a good basis for changes in schools that can help reduce teacher stress.

This article looks at the meaning and nature of teacher stress, what causes it, and what can be done about it. There is little doubt that teacher stress is an area of international concern both in terms of being a focus of research looking at the nature of teacher stress and the processes involved, and in terms of the development and evaluation of policies and intervention strategies designed to reduce it (Kyriacou, 2011; Lambert and McCarthy, 2006).

Defining Teacher Stress

'Teacher stress' originated as a short-hand term for occupational stress among schoolteachers, although it can also be applied to teachers working in other educational settings. The term 'stress' became widely used in occupational settings during the second half of the twentieth century. Unfortunately the term 'stress' can be used in a variety of ways, and this has led to a diversity of definitions of teacher stress.

Firstly, it can be used to refer to the level of demands and pressures that teachers face. Secondly, it can refer to the emotional, physiological, and/or behavioral response to such demands and pressures. Thirdly, it can refer to the degree of mismatch between the level of demands and pressures that teachers face on the one hand, and their capacity to deal with such demands and pressures on the other hand. Moreover, within each of these three main types of definition, researchers have embellished features of their definition in particular ways.

The second of these of types of definitions, in which teacher stress can be defined as "the teacher's experience of negative emotions such anxiety, frustration, tension, anger and depression, in response to the demands and pressures they face in their work as a teacher," is the most popular definition that has been adopted by researchers looking at teacher stress. It is this definition of teacher stress that is adopted in this article.

A number of theoretical models of stress in general and of occupational stress more specifically have been developed (Kyriacou, 2000; Langan-Fox and Cooper, 2011; Rogers, 2012). This has enabled us to get a clear picture of the nature of teacher stress. At the heart of applying such models to teacher stress is a focus on how a teacher perceives aspects of their working situation. All teachers face a range of demands. The nature and level of demands they face, how important it is to meet these demands, and the level of quality at which these demands need to be met are all partly influenced by external sources of pressure (from the school principal, students, parents, colleagues, and government agencies) and partly by the teacher's own expectations, beliefs, and values concerning their professional practice.

Teacher stress, in terms of the experience of negative emotions, is triggered by a perception that involves three key elements:

- The demands the teacher is facing are important (e.g., examination scripts need to be marked by the given deadline, a student misbehaving in the classroom needs to be controlled, and technical equipment needs to be checked before the lesson starts).
- Meeting these demands is difficult (e.g., this may be as a result of the teacher's view about their own ability, other aspects of their workload, and time pressures linked to other priorities).
- Not meeting these demands at a satisfactory level will have adverse consequences (e.g., impaired self-perception or how they are perceived by others, complaints by colleagues, students or parents, and impaired chances for a promotion).

If one of these three elements is missing from the situation, because the demands are not important, or the demands can be met easily, or not meeting the demands will have no adverse consequences, then teacher stress is not triggered.

There are several other terms in common use that have strong links with or conceptual overlap with teacher stress. These include teacher job satisfaction (or more specifically job dissatisfaction), teacher morale, teacher well-being, and teacher burnout. Of these, teacher burnout is the most important (Vandenberghe and Huberman, 1999). Teacher burnout is viewed as a syndrome of physical, emotional, and attitudinal exhaustion toward one's work, which results from experiencing teacher stress over a long period. In essence the teacher experiencing burnout no longer feels engaged with their work, as evidenced by a lack of energy, enthusiasm, and commitment. While early studies of teacher burnout focused on experienced teachers, more recent studies have identified that symptoms of burnout can be evident at an early stage of a teacher's career, including during the preservice period of initial training.

The Measurement of Teacher Stress

Measuring teacher stress has posed researchers with a number of problems. If teacher stress is essentially an emotional

experience, then we need to consider how well one teacher's report of how much stress they are experiencing equates with another's in a way that is both reliable and valid. If one teacher views being mildly annoyed as an indicator of a high level of stress and another views waking up each night in a state of panic as not a sign of stress, then the data collected will need to be regarded with suspicion. Fortunately, research studies using such measures appear to be fairly robust.

The most frequently adopted method of exploring teacher stress has been to ask teachers to complete a questionnaire. This will typically contain questions about their level of stress, the main sources of stress they experience (in terms of intensity and/or frequency), and what strategies they have adopted to reduce their level of stress. Over the years cross-referencing of research findings using different types of questionnaires and other methods of data collection (e.g., interviews, self-reported or observed behavioral indicators, and physiological measures) have provided a degree of confidence in the measures used.

Using such measures with data sets to compare groups (e.g., male vs female teachers), or to investigate a particular context (e.g., beginning teachers, special education teachers), or to drill down to the level of the individual teacher as part of a case study approach has proved to be very successful. In addition, such measures have allowed researchers to explore the relationship between teacher stress and a host of other variables that influence the processes involved in generating teacher stress (Helms-Lorenz et al., 2012; Klassen, 2010; Liu and Onwuegbuzie, 2012).

The Extent of Teacher Stress

Questionnaire data using a stem question such as "In general, how stressful do you find being a teacher?" coupled with a five-point rating scale labeled "not at all stressful, mildly stressful, moderately stressful, very stressful, and extremely stressful" has consistently indicated that between 20 and 30% of teachers report that being a teacher is either very stressful or extremely stressful. Some of the variability in the precise figure reported in different studies is a reflection of the setting of the study (e.g., the country or region within a country, the type of school, the type of students attending the school, and the time of year).

Comparisons have also been made between subgroups of teachers (e.g., beginning teachers vs experienced teachers, male teachers vs female teachers, well-qualified teachers vs less well-qualified teachers). While some studies have indicated differences between particular subgroups others have not, and there is no consistent pattern that has emerged regarding subgroup differences. Other data used as indicators of teacher stress have included levels of absence from work, mental health, physical symptoms such as aches and pains, heart rate, and levels of stress-related hormones.

Taken together, and comparing such data with other professional careers, being a teacher has been consistently identified as one of the high-stress professions, alongside being a nurse, a junior doctor, a social worker, a police officer, an air traffic controller, being in the clergy, working in journalism, and work as a theater artiste (Langan-Fox and Cooper, 2011).

The Main Sources of Stress Reported by Teachers

A wealth of research has been published that has enabled the main sources of stress reported by teachers to be identified (Carlyle and Woods, 2002; Kyriacou, 2011). These fall into the following 10 areas:

- administrative work;
- being appraised by others;
- career identity and development;
- classroom teaching;
- dealing with change;
- relationships with colleagues;
- relationships with pupils;
- targets and performance;
- working conditions; and
- workload.

In looking at the main sources of stress reported by teachers, we need to be aware that for a particular teacher their main source of stress may not figure as one that falls within one of the areas listed above. However, for that particular teacher their main source of stress may still contribute to an overwhelming sense of anxiety and frustration. As such, in dealing with teacher stress it is very important to consider each individual teacher's own unique pattern of sources of stress. Case studies based on a life-history approach, where teachers reflect on the ups and downs of being a teacher over several years or more, have been particularly fruitful in illustrating how the main sources of stress vary for each teacher over the course of their careers.

Action to Reduce Teacher Stress

There are two aspects to reducing teacher stress. The first concerns the strategies used by teachers to reduce their level of stress. These are referred to as 'coping actions.' The second concerns what others can do, be it as senior managers in the school, local, regional and national level advisers, policy makers, and those who design and deliver intervention programs, in order to reduce teachers' level of stress (Hayes, 2006; Kyriacou, 2000; Robins, 2010).

Coping actions fall into two main categories: direct action strategies and palliative strategies. Direct action strategies refer to things that a teacher can do either to reduce the likelihood of the source of stress occurring in the first place or to deal with it effectively so that its occurrence is short-lived. In contrast, palliative strategies do not deal with the source of stress, but rather focus on actions that can reduce the emotional experience of stress.

Direction action strategies are regarded as being the most effective as they deal with the source of stress directly. If a teacher experiences a high level of stress because they are finding it difficult to complete the required marking in time, there are several possible solutions – set less work that requires marking, engage students in marking each other's work, create longer gaps between when work is collected for marking and when it needs to be marked by, set aside more time at home to catch up on marking, manage one's time better so that less time is taken up doing things of lesser importance, systematize the

procedure for awarding marks better, share marking with a colleague, complete marking at a faster speed, and complete marking with less detail. If one of these strategies is effective in dealing with this source of stress, then its use as a coping action has been successful. Teachers often accept their situation as a given, rather than think carefully about how and why a particular source of stress occurs, and what changes in their practices can deal with this effectively. All sources of stress can be reduced by adopting practices that increase one's ability to deal with the demands involved more easily and effectively.

Palliative actions are sometimes also referred to as emotion control strategies. In essence, teacher stress involves experiencing negative emotions. There are a range of mental strategies and physical strategies that can lessen the experience of negative emotions. Mental strategies include putting the problem into perspective, looking at the humorous side of the situation, distracting oneself with more pleasant thoughts, not blaming oneself for the situation, being more realistic about what one can achieve, stopping oneself from overdwelling on the problem, and drawing on the emotional support of colleagues, friends, and family. Physical strategies include having a healthy lifestyle, adopting calming techniques such as deep breathing or relaxing muscles which have become tense, engaging in physical activities that are enjoyable (singing, swimming, jogging, eating, listening to music), and sleeping well.

In palliative coping strategies, the source of stress is still there – the teacher is still finding it difficult to complete the required marking in time. However, the teacher experiences less stress in this situation, because the feeling of anxiety and tension that was previously generated has now been mollified. While palliative coping strategies are important, they must not be seen as obviating the need to consider direct action strategies, as it is only the latter that can help generate better professional practice as a teacher.

A huge number of changes and initiatives have been introduced to reduce teacher stress (Rogers, 2012; Skovholt and Trotter-Mathison, 2010). These include preservice and in-service training courses and resources on how to deal with stress; stress reduction audits implemented by senior school managers to remove unnecessary sources of stress; and confidential advice and counseling for teachers experiencing stress. This can be contrasted with a situation a few decades ago where stress was not publicly spoken about, and a teacher experiencing stress would keep that information private, and probably view it as part of the job about which little can be done (other than changing to another job).

Conclusion

There is a wealth of research and other writings to draw upon which provides us with a clear understanding of teacher stress. This has created a basis for changes in schools both at an organizational level and at the level of the individual teacher's practice, for reducing stress. Unfortunately, there is little doubt that the bigger picture in most countries that frames teachers' working lives is one in which the demands made upon teachers and the degree to which their performance is held to account have been increasing. As such, the need to understand teacher stress and to apply this understanding to reducing teacher stress remains a major challenge for the education community.

Abstract

The status of teaching as a profession in the United States has changed in the twenty-first century. The landmark accountability legislation *No Child Left Behind* has challenged efforts to professionalize teaching, pushing it further from semiprofessional status. This article examines issues of teacher certification, the role of professional organizations, workplace conditions (including attrition and pay), and efforts to create staged teaching careers in this new policy environment.

Introduction

Historically, the work of teaching in the United States has been viewed as a semiprofession. With its roots as pink-collar work, ideal for women who sought employment before starting families, its status has been what Lortie (1975) famously described as "special but shadowed" (p. 10). The continued lack of consensus on a critical knowledge base; the blue-collared organization of the workplace; the absence of a centralized professional organization; and relatively low salaries have maintained this status over the years, despite repeated efforts to professionalize the work.

Nonetheless, the teaching profession has seen some notable changes in recent decades. The strong interventionist federal education policy of *No Child Left Behind* (NCLB, 2002), coupled with the dramatic rise in alternative pathways into the work, have changed everything from notions of expertise in teaching to workplace conditions. As a result, this special but shadowed profession has shifted further into the dark than the light.

In its essence, NCLB is an accountability policy that also sought to address persistent inequalities in students' access to good teachers. However, the simultaneous increase in regulations of instruction and related decreases in teacher autonomy, coupled with substantially eased entry requirements, resulted in an overall devaluation of teachers as professionals.

To describe the current state of the teaching profession in the United States, I look at common indicators of professionalism. Specifically, I describe the training and licensing for entry into the profession; working conditions, including issues of attrition, retention, and pay; and the notion of career.

Training and Licensing

A contradictory set of conditions has emerged when it comes to training and licensing teachers. The text of the NCLB legislation calls for 'highly qualified' teachers in every classroom; however, never before have so many alternative pathways to certification existed. This environment sends mixed messages about what it means to be a good teacher. The discourse of rigor is effectively undermined by policies that make for ever easier entry into the profession.

Defining High-Quality Teachers

The conception of teacher competence animating NCLB can be traced to the landmark 1966 Coleman Report, which found that school funding did not impact educational outcomes as much as teacher quality did. Part of what Coleman and his colleagues identified is what has come to be known as the maldistribution of qualified teachers. In the United States, poor children and children from historically underrepresented groups are disproportionately assigned to the weakest teachers – a situation that persists to this day (Ingersoll, 2003). International comparisons reveal that the United States stands out in this maldistribution problem: our country's disparity in students' access to qualified teachers is among the largest in the world (Akiba et al., 2007).

Coleman's formulation has had a continuous impact on notions of teacher quality. Numerous subsequent studies have verified positive associations between student achievement and teachers' academic qualifications. This relationship has been confirmed through correlations between student outcomes with teachers' scores on various standardized exams (Ballou, 1996; Ehrenberg and Brewer, 1994, 1995; Ferguson and Ladd, 1996; Mosteller and Moynihan, 1972); level of teachers' content knowledge, usually proxied through course-taking counts (Darling-Hammond, 2000; Goldhaber and Brewer, 1997, 2000); and years of teaching experience (Darling-Hammond, 2000; Murnane and Phillips, 1981; Rivkin et al., 2005; U.S. Department of Education, 2001).

NCLB is animated by this legacy as it aims to address the maldistribution problem by legislating a definition of teacher quality and mandating highly qualified teachers in every classroom. True to the Coleman Report's logic, highly qualified teachers are defined as those with full certification or licensure, a college degree, and demonstrated content knowledge in the subject being taught.

However, this legal definition has left much open to debate. For instance, in the description of *highly qualified teachers*, the word 'student' only appears once, and then only as a moderator for 'academic achievement standards.' In other words, the relational work of teaching is completely ignored. Social, emotional, and cultural knowledge does not come through the policy's text, nor does the specialized content knowledge teachers require to cultivate students' understanding – what Shulman (1987) called pedagogical content knowledge.

In light of these omissions, the definition of highly qualified teachers may not reach deeply enough into the qualities teachers need to best serve students living in poverty, thus potentially undermining part of the law's intent.

Research on teachers of students historically underserved by schools emphasizes the particular knowledge and qualities teachers need, including cultural knowledge (Gay and Howard, 2000; Ladson-Billings, 1999; Nieto, 1999), a commitment for social justice (Cochran-Smith, 2004; Oakes and Lipton, 1999), alongside identifying organizational features that support more equitable outcomes (Bryk et al., 2010; Lee and Smith, 1996). Furthermore, the law's emphasis on *teachers* and not *teaching* conflates teacher qualifications with quality teaching, which are not interchangeable (Kennedy, 2010; Little and Bartlett, 2010).

In the end, the *highly qualified teacher* clause sets a minimum standard given the pragmatic demands of legislation, but it falls short of more professionalizing notions of teacher quality. As Cohen (2011) argued, there is a huge difference between competence in rote instruction and what has been termed 'ambitious teaching' (Lampert and Graziani, 2009) – teaching that strives to include children in rich forms of content. The mapping between the qualifications outlined in NCLB and ambitious instruction is not obvious. Although research on teacher quality following the Coleman Report related teacher characteristics to student outcomes, ambitious teaching sets the bar higher. In one study, certification and formal education within a subject did not predict the use of ambitious teaching methods; however, the combination of subject training and subject-specific pedagogical training did (Smith et al., 2005).

Quality Teaching and Licensure

In the past two decades, the contribution of teacher training to quality education has been heavily interrogated. In the most damning of these indictments, Secretary of Education Rod Paige's 2002 *Annual Report on Teacher Quality* argued to redefine teacher qualifications to minimize teacher preparation. He referred to certification systems as 'broken' and 'burdensome' (p. 8), urging credentials to restructure to emphasize content knowledge and making student teaching optional.

Alternative Certification Programs

In the wake of this report, alternative certification pathways flourished. The latest estimates are that 20–30% of new teachers come from alternative certification programs (National Research Council, 2010). That is significant shift in the past two decades, enough to impact U.S. schools. Unlike traditional training programs, alternative certification programs typically accelerate preparation, often to fill a specific content, demographic, or geographic need. Thus Teach for America (TFA) publicizes itself as seeking to 'end educational inequity'; Troops to Teachers recruits former military personnel into schools in low-income communities; the New York City Teaching Fellows program solicits prospective teachers for 'New York City classrooms that need them the most.' Increasingly, some programs explicitly strive to diversify the mostly white teacher workforce (Humphrey et al., 2008). The main difference between these programs and traditional programs is the requirement of only few weeks of training before participants teach full time (Kee, 2012).

TFA has become one of the most visible and controversial of these programs. Founded in 1990, TFA recruits college graduates, typically without an education background, to teach in low-income rural and urban schools in exchange for a 2-year commitment. TFA's supporters point to its role in bringing outstanding college graduates into teaching, while its detractors decry the temporary workforce it brings to high-needs schools, contributing to their instability. Indeed, more than 50% of TFA teachers leave after 2 years and more than 80% leave after 3 years (Vasquez Helig and Jez, 2014). Compared to the overall attrition rate in teaching, estimated among new teachers in the first 5 years to be between 30 (Darling-Hammond, 2010) and 50% (Ingersoll and Smith, 2003), TFA's rate is high. If TFA and similar programs aim to alleviate the teacher shortage, the comparatively high turnover rates work against this goal. In fact, teacher turnover has been found to be detrimental to student achievement, with this effect felt most strongly in schools with high numbers of low-performing students (Ronfeldt et al., 2013).

Aside from the disruption experienced by children and staff, teacher turnover brings immense fiscal burden to districts (Smith and Ingersoll, 2004; Texas Center for Educational Research, 2000). Are alternatively certified teachers worth the expense and churn? Peer-reviewed research on the quality of alternatively certified teachers is not yet conclusive, but it converges on the idea that certification – especially pedagogical training – is consequential for teachers' overall efficacy (Darling-Hammond et al., 2001; Foote et al., 2011; SRI International, 2002; Wilson et al., 2001b). The preponderance of evidence points to teacher preparation as enhancing the initial effectiveness of new teachers, as well as increasing the likelihood that they will teach long enough to grow in that efficacy, since teachers' effectiveness has been shown to improve significantly after their third year (Boyd et al., 2005; Clotfelter et al., 2007).

The Response of Traditional Teacher Education

At the same time that alternative routes into the teaching have proliferated, traditional teacher education programs have responded to numerous criticisms about their efficacy by trying to increase rigor. Several decades ago, in response to reports from groups like the Carnegie Task Force on the Future of Teaching (1986) and the Holmes Group (1986), many teacher education programs increased certification requirements in subject matter preparation, coursework in pedagogy and diversity, and strengthened clinical experiences. There is some evidence that these efforts help novices feel better prepared, decrease attrition, and allow them to teach more effectively (Andrew, 1990; Andrew and Schwab, 1995; Baker, 1993).

The teaching profession suffers from a lack of consensus on the nature of expertise. Unlike other professions, teaching has multiple governing bodies with differing views on this issue, making such consensus doubtful. Just as formal teacher training is optional on the U.S. education landscape, professional accreditation of teacher education programs is likewise optional. Until recently, the two different bodies – National Council for Accreditation in Teacher Education (NCATE), the

Teacher Education Accreditation Council (TEAC) – existed, representing distinctive values on teaching. In 2013, the two bodies came together as Council for the Accreditation of Educator Preparation (CAEP); the new, sole specialized accreditor for educator preparation.

The new governing body will have to reconcile distinct history of the two organizations. The states and the profession created NCATE, the oldest and largest body, over 50 years ago. NCATE has long taken a leading role in efforts to professionalize teaching. NCATE had governed the majority of teacher education programs, with more than two-thirds of traditionally prepared teachers coming from their accredited institutions (Wise, 2005). Their goal is to use accreditation as a mechanism for supporting professional teacher preparation by judging the degree to which programs meet professional standards based on research consensus about quality teaching. NCATE has participated in developing licensing standards (2002), aligning tests to professional standards in addition to their evaluative work.

TEAC, on the other hand, supported a looser stance on teacher quality. A relative newcomer, TEAC was formed in the 1990s out of a task force of the Council of Independent Colleges, constituted by college presidents who wanted to develop a less intensive approach to accreditation (Wise, 2005). Unlike NCATE's clear standards, TEAC took an agnostic stance, permitting institutions to decide their own standards, eroding the notion of professional knowledge in the process. On the whole, the CAEP standards look more aligned to NCATE than TEAC (Council for Accreditation of Educator Preparation, 2013).

Teachers unions are also sources of professional legitimacy. For instance, the National Education Association, the larger of the two, has a stance in line with NCATE's. In a recent policy brief (2011), they called for 'profession-ready teachers' – teachers who are ready to support student learning from their first day on the job. Among their qualities, profession-ready teachers demonstrate appropriate subject matter knowledge, pedagogical content knowledge, and have completed classroom-based performance assessments. These provide uniform tools that allow teacher candidates to connect theoretical ideas about teaching to the classroom. Typically, teacher educators score these portfolios using standardized scoring rubrics (Darling-Hammond, 2006), giving them feedback on their programs.

Although some of the professional organizations assert a vision of professional teaching through expanded training and articulated visions of expertise, they are competing on a landscape that increasingly marginalizes their value. In this way, the debate about professionalism in teaching continues.

Working Conditions

To understand teachers' working conditions, it is critical to understand norms that have shaped and been shaped by school as a workplace. First, there is a longstanding norm of *egalitarianism* (Lortie, 1975; Smylie, 1992), the notion all teachers deserve the same status and recognition. The standardized salary scale rewarding time-at-the-job over performance exemplifies this norm. In the United States, teachers unions typically negotiate schedules to establish salaries that are based on teachers' level of education and time served. Second, scholars find a commonplace norm of *seniority* (Little, 1990), wherein leadership was assumed to arise from experience and veteran teachers got the choicest students and teaching schedules. Finally, a prevalent norm of *autonomy*, which Lortie (1975) observed long ago, manifests in a widely held assumption that teachers choose the particulars of what and how they teach.

Numerous observers of the teacher workplace have commented on the primacy of autonomy among these norms (Donaldson et al., 2008; Johnson, 1990; Little, 1988; Mangin, 2005). Once teachers are in their classrooms, they are not typically beholden to colleagues. Thus enormous instructional variability can be found even in the same school. Teachers also commonly display caution in soliciting and engaging colleagues' opinions and feedback.

Teaching is shaped by the bureaucratic structure of schooling. Bureaucracy necessitates sorting students in ways that stand to interfere with the democratic goals of education, particularly for students from historically underserved populations. Teachers committed to educational equity often embrace another set of norms, those of *change agents* as they work against the bureaucratic organization. They use their knowledge of children and commitment to communities to manage the tensions that arise out of schooling's usual social reproduction functions (Cochran-Smith, 2004; Gay and Howard, 2000; Hollins and Guzman, 2005; Ladson-Billings, 1995; Nieto, 1999; Oakes and Lipton, 1999). Whether teachers work with them or against them, norms both reflect and shape the school as a workplace.

Inequity in Working Conditions

Working conditions for teaching are highly variable, as U.S. schools differ enormously in the resources they provide to students and educators. As Kozol (1991) documented, the practice of funding schools through local property tax revenues has led to grossly unequal resources, from buildings to textbooks, in schools that are walking distance from one another. More recently, investments from middle-class families, through fund-raising work and volunteering, have exacerbated inequities, as parent associations support everything from building upkeep, arts programs, and other resources to augment local school budgets (Posey, 2012). For these reasons, challenging conditions prevail in schools serving students in poverty, with larger class sizes and fewer materials (NCES, 1997).

Despite these inequalities, schools as workplaces share common features that contribute to the semiprofessional status of teaching. Classrooms are the most crowded institutional settings (Jackson, 1968), and compulsory attendance makes teachers work for clientele who have varying interest in their services (Cohen, 2011). Teachers' schedules exhibit the inflexibility typically associated with blue-collar jobs and little of the flexibility associated with the professions (Goodlad, 2004). Contracts are generally arrived at through collective bargaining, making consideration for individual circumstances rare. Teachers commonly work beyond the contracted workday – especially if they take on ambitious forms of instruction (Bartlett, 2004). Taken together, these circumstances too often set any individual's efforts to take professional stance on

teaching against the grain of the institutional setting (Cochran-Smith, 1991).

Class sizes, school buildings, and resources have been recurring themes in research on school as a workplace for some time. In the wake of NCLB, however, new concerns arise. NCLB mandates accountability systems emphasizing school- and district-level growth targets as measured by standardized tests. Unfortunately, because performance on standardized tests has historically been linked to student socioeconomic status and parents' levels of education (Reardon, 2011), this means of accountability only increase the salience of school demographics to teachers' decisions to stay or leave, increasing turnover in schools already considered 'hard-to-staff' (Opfer, 2011). As NCLB takes hold in U.S. teaching culture, schools deemed low performing are publicized – and often stigmatized – since test scores are commonly announced in newspapers, even with individual teachers' ratings. NCLB has perversely created disincentives for teachers to work in poor communities: schools labeled as "low performing" find it increasingly hard to retain or attract teachers (Clotfleter et al., 2003).

Teacher Retention and Attrition

National concerns about the teacher workforce often focus on the issue of teacher turnover. Soon after Richard Ingersoll (2002) found that as many as 46% of beginning teachers left the profession within 5 years, the National Commission on Teaching and America's Future called teacher retention a "national crisis" (p. 21), highlighting the particularly high attrition rates among both new teachers and those working in schools serving historically underserved student populations.

When teachers describe their decisions to change schools or leave the profession, they often cite work conditions – resources, administrative support, student demographics, and school climate (Darling-Hammond, 1997; Rivkin et al., 2005; Ingersoll, 2002). Darling-Hammond (1997) found that more than one-quarter of school leavers cited dissatisfaction with teaching as a reason for their decision, with teachers in high-poverty schools more than twice as likely to leave because of dissatisfaction than those in more affluent schools. Teacher turnover, especially among new teachers, is typically due to low salaries, lack of administrative support, and student discipline problems (Guarino et al., 2006; Ingersoll and Smith, 2003). Although a number of studies have related teacher attrition to student demographics (Carroll et al., 2000; Scafidi et al., 2007), other studies suggest that teachers in demographically similar schools were more likely to leave because of differences in resources, decoupling student characteristics from other aspects of the work environment (Harris, 2002). Facility quality is an important predictor in teachers' decisions to leave, even after controlling for other factors (Buckley et al., 2005).

Teacher Quality and Teacher Attrition

In general, attrition and retention studies focus on the characteristics of the teacher labor force, the working conditions in schools, or a combination of these. Most of these studies do not attend to issues of teacher quality, even though the most optimal case would be retaining the best teachers (Guarino et al., 2006; Johnson, 2004). Recently, proxies for teacher quality have been used to investigate this question by investigating relationships between attrition and value-added to students' test scores (Boyd et al., 2009; Goldhaber et al., 2007; Hanushek et al., 2004). Alarmingly, some studies have found that the most qualified teachers leave the profession at greater rates (Boyd et al., 2005; Podgursky et al., 2004).

Aside from teacher effectiveness measures, teacher traits like minority status have been examined as they relate to attrition. Using the large-scale *Schools and Staffing Survey and the Teacher Follow-up Survey*, Connor (2011) found that by 2004–05, minority teacher turnover in the United States had become significantly greater than turnover among white teachers – although minority teachers were less likely than white teachers to exit schools in high-poverty areas or with large populations of minority students. In fact, minority teachers may be more inclined to stay in high-poverty schools if they have explicitly humanistic missions (Achinstein et al., 2010), suggesting that the intrinsic rewards of teaching (Lortie, 1975) still matter.

Induction

One effort to retain teachers comes in the form of induction programs. These typically provide beginning teachers with different forms of support during their first years of teaching. In their review of research on induction programs, Ingersoll and Strong (2011) found that, on the whole, support programs for new teachers had positive impacts on three outcomes: teacher commitment and retention, classroom instruction, and student achievement. Literature on effective induction programs suggests certain features increase their efficacy. First, new teachers should have mentors to help them navigate typical problems they face (Feiman-Nemser, 1983, 2001; Gold, 1996; National Commission on Teaching and America's Future, 2003; Veenman, 1984). Ideally, the mentor–mentee relationship should be a trusting one (Daloz, 1986; Gold, 1996; Villani, 2002). Mentors should offer assistance around the particulars of teaching – planning, instruction, management – and opportunities to observe, provide feedback on instruction, and connect to resources for selecting and adapting materials (Darling-Hammond, 1999; Evertson and Smithey, 2000; Feiman-Nemser, 1983; Holloway, 2001; Humphrey et al., 2000; Wilson et al., 2001a). Finally, in keeping with the norms of autonomy, effective mentors also know when to grant mentees their privacy and independence (Little and McLaughlin, 1993). Although the qualities of a good mentor have been articulated in the literature, Kardos and Johnson (2007) found that these ideal arrangements are not typical of what new teachers experience in induction programs. Common shortcomings of induction programs include mismatches between mentors and mentees, inadequate classroom observation, infrequent opportunities for interaction – with these supports particularly absent in low-income schools or for teachers of mathematics or science.

Teacher Pay

Teacher pay is low compared to most college-educated professions. Flyer and Rosen (1997) maintained that between 1960 and 1990, the 'true' real wages of teachers, particularly for elementary teachers, declined in comparison with wages for other college graduates. The relative decline in pay compounds

staffing difficulties, since overall levels of compensation are associated with variations in teacher quality. Globally, Ladd (2007) found that, in higher salary OECD countries, the share of underqualified teachers is low (less than 4%) when compared to countries with lower salaries (more than 10% underqualified). Within the United States, this pattern also holds. For instance, Figlio (1997) used the Survey on School Staffing data to look at 19 large U.S. metropolitan districts to test the hypothesis that higher pay attracted more qualified teachers. When controlling for other district factors, higher paying districts more consistently attracted teachers from selective undergraduate institutions and with infield degrees. Other researchers have similarly found that teacher salaries are positively associated with retention (Podgursky et al., 2004; Hanushek et al., 2004; Kelly, 2004).

Educational economists have found that increases in pay result in higher student achievement. For instance, researchers found that increased teacher salaries produced larger effects in student achievement when compared to other expenditures (Greenwald et al., 1996; Ferguson, 1991). A longitudinal analysis across school districts found that students' educational attainment increased most in states and districts that invested in teacher wages (Loeb and Page, 2000).

However, bonus pay incentives seem less effective at addressing recruitment and retention issues, a strategy that numerous states have tried. Researchers found that money was less of an incentive to new hires than other work issues, such as opportunities for alternative certification or working conditions in schools (Liu et al., 2004).

Making a Staged Career

What has been called the 'career-less structure of teaching' is a long recognized obstacle to professionalization. As Lortie (1975) described, the limited opportunity for advancement makes teaching a flat career, with little differences in expectations between novices or veterans (Kardos and Johnson, 2007). In response, attempts to professionalize teaching often seek structures to signal professional advancement.

Second Stage Roles

In the 1980s, school districts created second stage roles for teacher leaders. These were intended to acknowledge expertise and create a mechanism for instructional improvement. Eventually, most of these second stage roles waned. Identifying expertise proved difficult, funding was short-term, and job responsibilities underspecified (Donaldson et al., 2008). With NCLB's demands for evidence for instructional improvement via measurable gains in student achievement scores, districts showed a renewed interest in school-level instructional expertise. A new wave of coaches and instructional leaders provided opportunities for second stage teachers (Boudett et al., 2005; Neufeld and Roper, 2003; Poglicino et al., 2003).

Advanced Certification

In response to the Carnegie *Task Force on Teaching as a Profession*, a nonprofit organization called the National Board for Professional Teaching Standards (NBPTS) was developed around the notion of a professional continuum in teaching. NBPTS describes its mission as "advanc[ing] the quality of teaching and learning by developing professional standards for accomplished teaching, creating a voluntary system to certify teachers who meet those standards and integrating Board-certified teachers into educational reform efforts" (NBPTS, retrieved 2014). By making advance certification, NBPTS institutionally recognizes the difference between novice and experienced teachers. Because NBPTS certification requires more rigorous performances than are typically expected in initial certification, some states and districts provided financial inducements for teachers to obtain them. These had varying aims. In some cases, teachers received bonuses for getting the credential while others specifically sought to bring NBPTS teachers into high-needs schools. With some variation in geography and content area, NBPTS certified supports increases in student achievement (National Research Council, 2008; Clotfelter et al., 2007; Harris and Sass, 2011). Also, on the whole, NBPTS teachers exhibit school-level leadership. In a social network analysis study, NBPTS certified teachers were sought out for instructional help more than their noncertified colleagues (Frank et al., 2008).

While the advanced certification may recognize advancement and expertise, it has done little to alleviate the maldistribution problem. In one study, researchers found that NBPTS teachers were more likely to be teaching in advantaged settings, suggesting that, once again monetary inducements to bring expert teachers into high-needs communities had not succeeded. With the NBPTS certified teachers, unequal distribution existed not only across school districts, but also within schools themselves (Goldhaber et al., 2007).

Workplace Authority

Teachers' agency in the workplace varies from school to school, depending, in part, on school size, administration, local norms, as well as the strength and character of the local teacher community (Talbert and McLaughlin, 1994). Historically, although teachers did not always have authority over their teaching loads or salaries, the norm of autonomy gave them enormous authority behind the closed doors of their classrooms.

The architects of NCLB may have underestimated the extent to which the increasing dependence on state and national standards has eroded this sense of autonomy. This has cut into authority in two ways. First, teachers have been told what to teach – and, increasingly, how to teach it (Gutiérrez et al., 2000). Second, the usually private work of teaching has been made public through the publication of student test scores. Although the details of instruction are still obscured, the results of instruction (student test scores disaggregated by teacher) are made highly visible to the outside world. Through *value-added modeling (VAM)*, teachers' job performance is estimated through statistical modeling of student performance gains based on achievement test scores (Corcoran and Goldhaber, 2013). These have caught the imagination of policymakers as an appealing alternative to more subjective teacher job performance ratings. Thus VAM has been at the heart of initiatives to link pay to performance. The promise of VAM has not been realized, however. In a randomized controlled trial, Springer et al. (2010) found that students whose teachers were eligible for

bonuses did not outperform students whose teachers were not. Aside from their effectiveness as incentives, VAM are not appropriate tools for the job (Haertel, 2013). Because of their instability within individuals over time, they may only be useful indicators of relative performance (very high or very low).

Teaching Economics

Micheal Moos van Wyk, College of Education, University of South Africa, Pretoria, South Africa

Abstract

We are living in a complex world which is faced with enormous economic challenges. The purpose of economic education is to create responsible citizens and effective decision makers. The importance of economic education goes far beyond the goal of improving an understanding of the basic principles of supply and demand and the workings of the economy. Economics can be taught by generating new knowledge with the help of exposing students to real-life learning environments and experiences. Teaching economics in this twenty-first century requires teachers to implement effective technology-integrated teaching and learning teaching, and assessment strategies not only to achieve cross critical outcomes, but providing ongoing support to the digital natives.

Introduction

Economic education focuses on the scholarship of teaching and learning economics as a subject. It encompasses the content to be taught, methods of teaching, evaluation of those methods, and information of general interest to teachers of economics in elementary through graduate school. Economic education is extremely important because it is vital to the future health of our nation's economy. The purpose of economic education is to create responsible citizens and effective decision makers. Economic education is a very crucial subject that many of our nation's schools tend to overlook. The importance of economic education goes far beyond the goal of improving an understanding of the basic principles of supply and demand and the workings of the economy. Economics can be taught by generating new knowledge with the help of exposing students to real-life learning environments and experiences. Students develop perceptions of their economic world at an early age, which, as they progress through the educational process, develop into attitudes and opinions about the subject of economics. Intended or not, teachers influence the direction of attitude development. By finding ways to teach students more about economics, teachers are contributing to improved attitudes toward the subject. By teaching basic economic concepts and applying them to classroom discussions of economic issues and institutions, teachers and lecturers are not indoctrinating students, but providing a knowledge foundation for more informed student opinions and decision making on vital economic issues. The more economic concepts students know, the more they like and value the subject and the more information they have about economic issues. Students who do not get the opportunity to learn economics and increase their economic understanding will probably never take much interest in the subject or in their economic world.

Organizations Promoting Economic Education

Council for Economic Education (CEE) – the United States

The Council for Economic Education (2009) (the new name, since January 2009, of the National Council on Economic Education) is a national nonprofit organization "committed to empowerment and opportunity through economic and financial literacy". The mission of the CEE (2009) is twofold: to advocate for better and greater school-based economic and personal finance education at the kindergarten through 12th-grade levels (K-12); and to educate young people in the United States and around the world, primarily through well-prepared teachers, so they may become empowered with economic and financial literacy. The National Council on Economic Education (NCEE) is a nationwide network in the United States that aims at promoting economic literacy among learners and their teachers. The NCEE's mission is to help learners develop the real-life skills they need to succeed: to be able to think and choose responsibly as consumers, savers, investors, citizens, members of the workforce, and effective participants in a global economy (NCEE, 1995, 2005). The NCEE *AmericaEconomics* and *InternationalEconomics* (Train-the-Trainers and Writers) programs prepare teachers/lecturers to conduct professional development for teachers of economics at school and university level. The *Train-the-Trainers* program consists of four one-week seminars, each of which focuses on strengthening participants' knowledge and skills of both economic concepts and pedagogy (NCEE, 2005). According to a survey compiled by the NCEE titled *Survey of the States. Economics and personal finance education in our nation's schools in 2007*, there is still much that needs to be done in terms of implementing economic education into our nation's schools. The CEE conducted a follow-up survey called *Survey of the States 2011: The state of economic and personal finance education in our nation's schools*. The 2011 survey reported several key findings:

- The number of states that now require students to take an economics course as a high-school graduation requirement increased from 21 in 2009 to 22 in 2011.
- However, only 16 states require the testing of student knowledge in economics, 3 fewer than in 2009.
- No improvement has been seen in the area of personal finance. The number of states that require students to take a personal finance course (or personal finance included in an economics course) as a high-school graduation requirement remains at 13.
- Only 2 more states now require that personal finance content standards be implemented, bringing the total to 36.

Visit www.surveyofthestates.com to explore the interactive Survey of the States.

Annamaria Lusardi, Denit Trust Professor of economics and accountancy at the George Washington University School of Business, concurred on the above statements and said:

> Just as it was not possible to live in an industrialised society without print literacy – the ability to read and write – so it is not possible to live in today's world without being financially literate. To fully participate in society today, financial literacy is critical.

The Survey of the States is a biennial report that brings attention to the critical importance of economics and personal finance education by documenting its status in the 50 states and the District of Columbia.

In the next paragraph, an example of an organization promoting economic education in a developing economy, the South African Foundation for Economic and Financial Education (SAFEFE), is discussed.

South African Foundation for Economic and Financial Education (SAFEFE)

The NCEE's (now CEE) entry point in South Africa in 2004 was through Professor Claudia Parliament's connection with the University of the Free State (UFS), Bloemfontein. During initial discussions in Lithuania in 2004 between the Council and UFS delegates, it was decided to develop partnerships to strengthen economic delivery systems firstly in the Free State province and soon expanding to the whole of South Africa and later also to the South African Development Communities (SADC) region. In 2008 the South African Foundation for Economic and Financial Education (SAFEFE, 2008) was established as a nongovernmental organization focusing on economic and financial education for K-12 teachers and university lecturers. SAFEFE is now legally organized and has a board of directors, a strategic plan, and a representative group of *Training of Trainers* and *Training of Writers* alumni to assist in the planning and delivery of professional development programs. SAFEFE focuses on seven activities which are seen as priorities: teacher development; material development; partnership building with the national Department of Education and higher education institutions; fundraising; networking with teachers; competitions for learners; and international networking. Currently SAFEFE provides seminars in professional development and other supported services to more than 260 000 economic teachers (grades 4–12), 1200 economics and management sciences and economics subject advisers in all nine provincial departments of education, and several economics lecturers at 18 universities in South Africa.

Integration of Teaching Methods and Media in Teaching Economics

Applying Creative and Innovative Teaching Methods

Economic education is a growing subject in secondary education. The current teaching strategies that are implemented by economic teachers at the high-school level are outdated and do not pertain to the ways in which students best comprehend economic content. Excellent and effective teaching demands a host of devices, techniques, and strategies not only to achieve cross critical outcomes, but because variety, itself, is a desideratum. Prior to looking at the many different teaching strategies, we must first look at why educators struggle with the teaching of economics through the many different strategies available. First and foremost, educators are not adequately educated themselves in terms of economic education. Social studies educators are generally the ones who are responsible for teaching high-school economics courses and the typical social studies educator on average has only completed four to eight credit hours of economics course work. This represents no more than 7% of the total social science hours required for certification (Joshi and Marri, 2006). How can we expect these educators to effectively teach our youth the knowledgeable skills and content of economics when they in fact do not have the requisite knowledge and skills themselves? The literature suggests several teaching strategies that actively involve students in the content, including collaborative problem solving, service learning, interactive role play and simulations, an inverted classroom, experiments/demonstrations/dramatizations, technology-based teaching strategies, and lecturing accompanied by student-centered activities. It is imperative that teachers utilize many teaching strategies and not just limit themselves to a specific one (Goffe and Sosin, 2005). This will allow them to target the many different learning styles their students have, as well as to create a learning environment that will keep their students actively involved as opposed to the same daily routine. Overall, effective teaching styles provide an effective learning environment in the classroom and enable students to apply classroom learning to real-life situations.

In 1995, 2000, 2005, and 2010 national surveys of US academic economists were conducted to investigate how economics is taught and assessed in four different types of undergraduate courses. In this paper we present the first basic results from the 2010 survey to identify persistent patterns and a few gradual changes in teaching and assessment methods. Despite calls for economists and other post-secondary instructors to make greater use of active, student-centered learning methods over the past two decades, 'chalk and talk' has remained the dominant teaching method in all types of undergraduate economics courses. But there is evidence of slow drops in mean (though not median) values for those variables, and of gradual growth in the use of some new teaching methods, including instructor-directed class discussions and computer-generated displays (such as PowerPoint). More instructors provided students with a prepared set of class notes; computer lab assignments were increasingly common in econometrics and statistics courses; and the Internet database searches were used by a growing (though still small) minority of instructors in all types of classes. Classroom experiments are used by a small share of instructors in introductory courses, but almost never in other kinds of courses (Bartlett, 2006). Calculus is still not viewed as important by a majority of economics instructors in any of the four types of courses, but for the 2010 survey these ratings were higher in intermediate theory and statistics and econometrics courses than in the

earlier surveys. Colander et al. (2004) compiled a book entitled *The changing face of economics* that gives a sense of the modern economics profession and how it is changing. The volume does so with a set of nine interviews with cutting-edge economists, followed by interviews with two Nobel Prize winners, Paul Samuelson and Kenneth Arrow, reflecting on the changes that are occurring. Emanating from this source is a clear picture of today's economics – and it is no longer standard neoclassical economics. The interviews and commentary together demonstrate that economics is currently undergoing a fundamental shift in method and is moving away from traditional neoclassical economics into a dynamic set of new methods and approaches. These new approaches include work in behavioral economics, experimental economics, evolutionary game theory and ecological approaches, complexity and nonlinear dynamics, methodological analysis, and agent-based modeling. One of the current problems with economic education is the strategies teachers use to teach the subject. The majority of teachers are stuck on traditional methods that have been in practice for many years. A specific example would be the chalk-and-talk method, which is defined as a traditional method of education in which the teacher addresses the students and uses the blackboard to provide examples or illustrations (Joshi and Marri, 2006). Another example that is very similar to chalk and talk is lecture, another method of direct instruction. Many students who take economics classes get very bored and uninterested in the material taught because of these outdated teaching methods. If teachers were able to use more effective methods in the economics courses they teach, their students would be able to better comprehend the information making them better citizens of not only the United States but the world as well. The issue is that academics cannot teach the same way they were trained a decade ago but need to make the paradigm shift to accommodate the diverse M-generation student population in their teaching styles which enters universities globally.

Service-Learning Approach in Teaching Economics

Service-learning (SL) is a well-established pedagogy used by college and university faculties for over two decades (Stanton et al., 1999). Economists have used SL to promote deep learning in economics classrooms for over a decade (McGoldrick, 1998; Simmons, 2003). Due to the flexibility of this pedagogical technique SL can be used in a multiple of ways in a variety of classroom settings. Scholars of the theory of SL reported that it is an effective tool for teaching economic theory (McGoldrick, 2002; McGoldrick and Ziegert, 2002). McGoldrick (2002) conducted a study by using SL in teaching economics and reported how participants learned to apply economics matter to real-life situations. SL is an approach to learning-by-doing that highlights the social relevance of the work performed by universities. It can be regarded as an augmentation of the concept of community service with the inclusion of a learning component that may carry academic credits or may be part of a specific course requirement (Rhoads, 1997; Mungaray et al., 2007). The fundamental idea is that students learn and develop themselves through active participation in communitarian experiences organized and led by faculty, where they have the opportunity to apply the concepts and instruments recently acquired to help their community (Yates and Yuniss, 1997). More formally, SL is a method of experiential learning that links the classroom with the local community, and requires students to spend time in volunteer service and relate their experiences to the educational knowledge they see in the classroom. For the economics discipline, SL provides a complementary teaching strategy that can motivate learning through experiences that make a social contribution. Furthermore, it is a method by which economics can be made more accessible to an increasingly diverse student body and improve the relationship between colleges and universities and their communities.

Technology-Integrated Media

Some circumstantial evidence suggests that declining numbers of economic majors at the tertiary levels in the 1990s led academic economists to devote more time and energy to teaching. Until the late 1999s, economists paid little attention to changing the way to create more participative teaching methods and strategies to enhance student learning in the classroom. Some academic economists spoke of 'exposing' students to concepts and 'imparting' knowledge, but what was the use for this stance? Most lecturer rooms were used for the transmittal of factual information through textbooks and demonstrations of mathematical and graphical constructions. The lecture, textbook, PowerPoint and blackboard were the simplest delivery modes and teachers of economics used little else (Becker and Watts, 1996). Arnold Katz and William Becker (1999) reported in an article entitled *Advancing the integration of new technologies into the undergraduate teaching of Economics* that the subject is lagging behind other disciplines in creating innovative ways that engaged students more actively in the learning process. In the 2000s a renewed impetus was injected into more research on the use of technology-integrated teaching and learning of economics to undergraduates. Another variation of online communication that is increasingly used in economic education is interactive software for groups working on the Internet. The *ComLabGames* (http://www.cmu.edu/comlabgames) are effective tools whereby students learn game theory with specialized software over the Internet. In some cases, students can play games with other students at remote sites. Such software is similar to 'massively multiplayer' games where hundreds of thousands can interact online. Currently, some of the leading online games are 'Sims Online' and 'Ultima.' More research studies focused on areas related to computer simulations and modeling, machine-based tutoring, laboratory supplements to lecture course, Web-based learning environments, multimedia teaching enhancements, collaborative learning techniques, classroom experiments, social media networking, evaluation and assessment, interdisciplinary instruction, and institutional resource sharing of open educational resources.

Dirk Mateer designed an online website, *Starting point: teaching and learning economics*, to assist economists in developing innovative teaching strategies. This e-learning platform illustrates the benefits of using multimedia to reinvigorate the way to teach economics. The use of media to enhance teaching and learning complements traditional approaches

to learning. Effective instruction builds bridges between students' knowledge and the learning objectives of the course. Using media engages students, aids student retention of knowledge, motivates interest in the subject matter, and illustrates the relevance of many concepts (Mateer, 2011). Students have different learning preferences. While those with a background in science or mathematics may have a comparative advantage in understanding the quantitative aspects of economics, research shows that people learn abstract, new, and novel concepts more easily when they are presented in both verbal and visual form (Salemi and Walstad, 2010). Visual media also make concepts more accessible to a person than text alone, promote deep learning rather than rote learning, and help with later recall (Willingham, 2009). The use of media is beneficial for teachers and students alike. Technology plays an important role in creating an interactive learning environment, which prompts two-way discussion in the form of student-created content (Goffe and Sosin, 2005; Bransford et al., 2000). An excellent list of technology activities for teaching economics can be accessed using the Journal of Economic Education's online section at http://www.indiana.edu/-econed/onlinehome.htm. Media are ideal for illustrating complex ideas in a short period of time, connecting learners with events that are culturally relevant and theories taught in the classroom with real-world events and policies (Mateer, 2011). Using social media of popular culture familiar to students is likely to (1) maintain attention and student interest in the theories and concepts being taught; (2) develop better analytical skills by analyzing media using the theories and concepts they are studying; and (3) break down the barrier between formal learning and understanding, enabling students to see concepts and new examples when they use these same media in their private life (Mateer, 2011). Some economics blogs are created to express the strong viewpoint of the owner, which may be a minority or even crank opinion on an economics issue. Yet, this diversity in viewpoints could be used as an excellent opportunity for teaching critical thinking, with a clear role for the instructor in helping students evaluate, compare, and summarize. A list of economics blogs can be found in the section of Resources for Economists on the Internet devoted to them at http://rfe.org/Blogs. Before using audiovisual materials in teaching, one should have an understanding of copyright, which by default applies to materials found on the web. The Economics Network's *The handbook for economics lecturers* provides useful instructions on this issue. Permission to use these materials might be requested directly or granted in advance using a license such as Creative Commons (Poulter, 2010). The biggest hurdle in using audiovisual materials – aside from a willingness to do so – is the workload involved and the skill in recognizing content that will enhance learning, instead of becoming a distraction (Mateer, 2011). Several sites are available such as *The mathematics for economics: enhancing teaching and learning* (METAL), *TED-talks* are well-produced video lectures on themes as diverse as business climate, developmental economics, environmental issues and globalization, Mateer created *Teaching economics with YouTube* to showcase in-class videos, *Economics in the movies*, *TV for economics*, *From Abba to Zeppelin*, *Led* (Hall et al., 2008) and *Flash music for economics*. The benefits of using multimedia in the classroom are well established in the academic literature but, as a discipline, economics has been slow to adopt innovative approaches to teaching (Becker, 2004; Becker and Watts, 1996, 2001a, b). Media can be used in almost any discipline to improve student learning in a variety of forms, both in class (lectures and tutorials) and out of class (homework, offline/online assignments, essays, and projects). Research shows that the use of multimedia or popular culture can stimulate discussion in introductory classes (Becker, 2004), illustrate basic concepts (Hall, 2005; Hall and Lawson, 2008), and explain abstract concepts like game theory (Dixit, 2005) at an advanced level.

Assessment Practices in Economic Education

Schaur et al. (2008) conducted a survey on *Assessment practices and trends in undergraduate economics courses*. Findings revealed that there was an increased use of multiple-choice questions in all types of undergraduate economics courses, after taking into account the greater use of most types of written assignments and student presentations, and the stable class sizes in these courses from 1995 to 2009. They further concluded that economists have been cutting back on the time and care they devote to assessment. Instead, the general picture is that economists are making greater use of assessment practices that have been more popular for some time in other academic fields. Lastly, it is reported that, although 'chalk and talk' is found to remain, by far, the most prevalent form of instruction in undergraduate economics classes, there is finally some evidence of movements in undergraduate economics courses toward greater use of student-centered teaching methods that are more commonly used in other subject areas. On the other hand, Myers et al. (2011) reported in a survey conducted on the *Assessment of the undergraduate economics major: a national survey* that more instructors did use performance in games, simulations, and classroom experiments for grading purposes, given the rising popularity of experimental economics during this period both as a research field and as a teaching method. Several commercial and academic websites and books on classroom experiments appeared during the period that the three surveys were conducted (http://veconlab.econ.virginia.edu/admin.htm), making it easier for instructors to use classroom experiments. But part of the explanation for this result may simply be that classroom experiments, simulations, and games are often used solely as motivational and pedagogical exercises, and not for assessment.

Another trend shows that economics departments are faced with growing demands to document what their graduates have learned on completion of the undergraduate major (Steven et al., 2011). The results of a national survey of economics department chairs in the United States reveal that nearly two-thirds of the departments have a formal assessment plan (Myers et al., 2011). There is substantial agreement on the most important student-learning outcomes, which are consistent with the Hansen proficiencies. The most common approaches that departments employ to measure learning outcomes are course-embedded assessments and senior exit surveys. Capstone courses and senior projects as program assessment methods are most common in departments that

are not in business schools and are without doctoral programs. Finally, more than half of the departments have adjusted their curriculum based on the results of their own assessment plans.

Conclusion

We are living in a complex world which is faced with enormous economic challenges. Economic education is the study of the scholarship of teaching economics effectively. It encompasses the *what, how and why* we teach economics in relation to the content, teaching methods, assessment in elementary schools and universities. Understanding this world requires education in basic economic concepts and their application to a multitude of economic issues. As students grow and learn, economic attitudes and opinions take shape and influence thoughts and actions over a lifetime. Consequently, academics and teachers need to know the nature of the relationship between attitudes and opinions in economics learning. Despite the increasing use of multiple-choice questions in all types of undergraduate economics courses, after taking into account the greater use of most types of written assignments and student presentations, and the stable class sizes in these courses from 1995 to 2011, we do not conclude that economists have been cutting back on the time and care they devote to assessment practices. Moreover, the general picture is economists and teachers of economics use more effective and applicable assessment tasks and practices that have been for some time employed in other subjects. Subsequently, economic education in schools and at universities is shifting from a predominantly academic approach toward more emphasis on teaching that meets the needs of students in their current and future lives. The challenges and opportunities in teaching economics in the twenty-first century and beyond are immense but we must not lose focus by empowering students to use economic knowledge in their daily life. Because of the global challenges, we must therefore educate students to be creative in becoming responsible citizens, effective change agents, and decision makers.

Teaching for Metacognition

Marcel VJ Veenman, Institute for Metacognition Research (IMR), Hillegom, The Netherlands; and Leiden University, Leiden, The Netherlands

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Metacognition concerns the descriptive knowledge of, and the operational control over one's cognitive processes. Together, these two components of metacognition constitute a student's repertoire of metacognitive self-instructions for the regulation of cognitive performance. Developmental trajectories of metacognition show that the repertoire of self-instructions becomes general by the age of 14, that is, across tasks and disciplines. Students, however, substantially vary in the adequacy of their metacognitive skills. In metacognitive-deficient students, both descriptive and operational components need to be explicitly taught in order to build up an organized repertoire of self-instructions. Conditions for effective training are being discussed.

Defining Metacognition

When Flavell coined the term in the 1970s, metacognition was conceptualized as cognition about cognition, or thinking about thinking (Flavell, 1979). This definition emphasized that metacognition takes one's own cognitive processes as the object of thought. Initially, the concept of metacognition was confined to descriptive knowledge about one's cognitive system, such as knowledge about how memory works. The assumption was that a better understanding of one's cognitive functioning would yield more adequate behavior. Subsequently, Brown and DeLoache (1978) added a self-regulation component to metacognition, referring to the control over one's cognitive behavior. According to this regulatory perspective, skillful planning and monitoring of one's behavior would be responsible for successful performance. Current definitions still reflect the contrast between a descriptive-knowledge component and a regulatory component of metacognition, respectively, referred to as metacognitive knowledge and metacognitive skills (Dinsmore et al., 2008; Veenman et al., 2006). Both components, however, are required for adequate metacognitive control over one's cognitive processes.

Wang et al. (1990) concluded from a literature review that metacognition is the most important predictor of learning performance. Moreover, in a recent overview of studies with students of different age, performing different tasks in various domains, metacognitive skillfulness accounted for 40% of variance in learning outcomes (Veenman, 2008). Students show substantial individual differences in metacognitive skillfulness. The undertow of this conclusion is that some students are deficient in metacognition, which deficiency could be relieved by teaching for metacognition. The ultimate question is what should be taught, and how.

Metacognitive Knowledge

Metacognitive knowledge concerns one's descriptive knowledge about the interplay between person, task, and strategy characteristics (Flavell, 1979). For instance, a person may think that he or she (person characteristic) is poor at recollecting names of people (task characteristic) and, therefore, that he or she should devote attention to rehearsing names (strategy characteristic). Yet, another person may positively appraise his or her capacity for retention of names, thus putting less effort into memorizing them. The second person, however, not necessarily has a better memory for names than the first person. Metacognitive knowledge can be either correct or incorrect as one may underestimate or overestimate the actual level of competency, relative to the complexity of the task (Veenman et al., 2006). One person may be embarrassed when addressing someone with the wrong name, whereas another person may erroneously disregard such memory failure. These two persons are likely to differ in estimations of their memory competency.

Metacognitive knowledge rests on a personal belief system that is built up from metacognitive experiences in the past and individual attributions of causes and consequences (Flavell, 1979). For instance, the metacognitive experience of forgetting another person's name evokes a negative attribution about one's capacity for recollecting names. As belief systems are tacit by nature, they are rather resistant to change (Veenman, 2011). Counter experiences may go unnoticed or they may be framed into existing attributions. Given the imperfection of attributions in the belief system, metacognitive knowledge may be inaccurate or flawed. Nevertheless, a person has to make behavioral decisions based on the available metacognitive knowledge, for better or worse.

Metamemory

Metamemory was discerned first as metacognitive knowledge (Flavell and Wellman, 1977). Initially, metamemory only referred to the descriptive knowledge of one's memory system and of strategies that affect memory processes. Acquisition of factual knowledge about memory processes was assumed to improve memory performance. Later, the focus of metamemory research shifted from the knowledge product to the process of metamemory (Nelson and Narens, 1990). Feeling of Knowing (FOK) and Judgment of Learning (JOL) refer to a student's predictions about future test performance, either on items that have been studied (JOL), or on novel items (FOK). A student's individual level of metamemory accuracy is expressed by the alignment of one's predictions with actual performance on a series of items (e.g., vocabulary items). The more accurate the

student is, the better he or she can decide whether or not further study of items is required. Thus, the monitoring or evaluation of memory contents is a key feature of metamemory. In fact, monitoring and evaluation are metacognitive skills that can be trained in order to facilitate metamemory accuracy.

Metacognitive Conditional Knowledge

Another specific type of metacognitive knowledge is conditional knowledge of strategy use (Schraw and Dennison, 1994). Conditional knowledge pertains to descriptive knowledge about when a particular strategy should be applied. Poor students often are ignorant of potential strategies. For instance, they do not know what goal setting and planning stand for, or when to apply these strategies. Knowing what to do when are the conditions for strategy use. Even when students have obtained adequate conditional knowledge, it does not guarantee the actual execution of a strategy as students may still lack the knowledge of how the strategy should be enacted. In fact, conditional knowledge is an overture to skill acquisition, where a metacognitive strategy has to be consciously applied step-by-step and gradually transformed into a skill through practice (Veenman, 2011). Thus, conditional knowledge is a prerequisite, but not sufficient condition for the acquisition of metacognitive skills.

Metacognitive Skills

Metacognitive skills refer to operational knowledge that is required for the fluent regulation of, and control over one's problem-solving and learning behavior. Orientation, goal setting, planning, monitoring, evaluation, recapitulation, and reflection are manifestations of metacognitive skills that directly affect learning behavior and, consequently, learning outcomes (Veenman, 2011). In metacognitive capable students, skills appear in an orderly sequence of preparatory activities at the onset of a task, systematical execution of activities during task performance, and evaluation and reflection at the end of the task.

At the onset of studying text, skilled students thoroughly read the assignment, pay attention to the title and activate prior knowledge about the topic of the text, scan the text for subheadings and structure, and set a reading goal and devise a reading plan related to the goal (e.g., the goal of understanding relations between main concepts may be effectuated in a plan to make schemas of main concepts and their relations). During reading, they monitor their understanding of words, phrases, and paragraphs. If necessary, they deliberately navigate forth and back through the text in search of information to resolve lack of understanding. At the end of the text, they summarize main conclusions, evaluate these conclusions against their original goal, and may reflect on their reading behavior in order to improve later text studying (Pressley and Afflerbach, 1995). Poor readers, on the other hand, skip the title and immediately start (technically) reading the text from start to end. They may misread words they do not know, without notice. They may bluntly recognize a lack of understanding, however, without doing something about it. At the end of the text, they simply stop reading and conclude that they are 'done.' A similar difference can be found in the problem solving of metacognitive skilled vs poor students (Van der Stel and Veenman, 2010). Good students read the entire assignment first, activate their prior knowledge about the problem content, determine what is given and asked for, make a sketch of the problem, set a clear goal for the outcome, and plan a course of action to reach that goal. They systematically follow their plan, or deliberately change their course of action when arriving at a deadlock position. They repeatedly check the correctness of intermediate results. Before submitting the answering, they evaluate their outcome against their goal and against the assignment. Poor problem solvers, on the other hand, only partially read the problem statement and tend to rush into the application of formulas without knowing what they are heading for. When they get stuck, one formula is simply exchanged for the other. This trial-and-error behavior makes it difficult to trace one's problem-solving steps and, thus, impede monitoring for mistakes and establishing whether progression is being made. When reaching an outcome, they are inclined to submit the answer without further considerations of its correctness or appropriateness. Obviously, many students can be positioned somewhere in between these two extremes. A major issue is how to account for these individual differences in metacognitive skillfulness.

Nelson's Model of Metacognition

Nelson (Nelson and Narens, 1990) distinguished an 'object level' from a 'meta level' in the cognitive system. At the object level lower-order cognitive activity takes place. For instance, lower-order processes needed for reading are decoding, parsing, and lexical access. Higher-order processes of evaluation and planning at the meta level govern the object level. Two flows of information between both levels are postulated. Information about the state of the object level is conveyed to the meta level through monitoring processes, while directions from the meta level are transmitted to the object level through control processes. Thus, if an error occurs on the object level, a metacognitive monitoring process will give notice of it to the meta level and control processes will be activated to resolve the problem. Metaphorically speaking, Nelson's model can be compared to a factory, in which the work floor represents the object level and the manager overlooking the work floor represents the meta level. The manager monitors activity on the work floor to detect errors that may obstruct the production process, in which case the manager's instructions to the work floor restore production. Basically, this is a bottom-up model because metacognitive control is triggered by anomalies in cognitive activity.

Metacognitive Skills as Self-Instructions

Veenman (2011) extended Nelson's bottom-up model with a top-down approach. Metacognitive skills are perceived as an acquired program of self-instructions for the control over and the regulation of cognitive activity at the object level (cf Gollwitzer and Schaal, 1998). This program of self-instructions is activated whenever the learner is faced with a task. Self-instructions can be perceived as condition-action rules that contain conditional knowledge about when to apply a skill and instructions for how to implement the skill on the object level (see **Figure 1**). For instance, activating prior knowledge can be represented as the

Figure 1 Metacognitive skills as a program of self-instructions. Adapted from Nelson, T.O., Narens, L., 1990. Metamemory: a theoretical framework and new findings. In: Bower, G. (Ed.), The Psychology of Learning and Motivation, vol. 26, pp. 125–173.

rule: IF you have read the task assignment, THEN retrieve all that you know about the topic from memory. In contrast with Nelson's view, self-instructions from the meta level are self-induced, that is, they need not necessarily be triggered by anomalies in task performance. The monitoring flow serves to identify which conditions are satisfied for activating self-instructions. Metacognitive skilled students have an orderly set of self-instructions available that will help them work through the task. The output of an implemented self-instruction will subsequently satisfy the conditions for the next self-instruction. Such a program of self-instructions is acquired through experience and training, much in the same way as cognitive skills are learned (Veenman, 2011). Some students may spontaneously pick up such a program of self-instructions from exemplary models in their environment (parents, teachers, peers), whereas others are devoid of, or not receptive to these models. Furthermore, the developmental trajectory of metacognition may impose limitations to metacognitive skillfulness.

Development of Metacognition

The development of metacognition has its early roots in Theory of Mind (ToM). ToM pertains to young children's knowledge about the mind and, in particular, to knowledge that the content of mental states, such as beliefs, desires, and intentions, may vary from one person to the other. Crucial to the development of ToM is the understanding of a child older than 4 years that another person may or may not know what the child knows. Longitudinal studies have shown that ToM at 4–5 years of age is a precursor of later metacognitive knowledge of metamemory at 5–6 years of age (Lockl and Schneider, 2006). Apparently, the notion that minds are separate entities is prerequisite to the development of metacognitive knowledge.

Development of Metacognitive Knowledge

From the age of 5 years on, children gain knowledge about their memory system. At first, metamemory knowledge pertains to the absolute limitations of their memory, but gradually children become more sensitive to the conditions of memory storage and retrieval. At the age of 6 years, children start to recognize the conditions for effective strategy use. This conditional knowledge becomes more accurate and fine-grained with the years. The adequacy of strategic behavior in young children, however, remains poor due to the immaturity of the prefrontal cortex in the brain (Crone et al., 2006). Young children are overly impulsive and they lack the cognitive capacity for planning their actions.

Development of Metacognitive Skills

At the age of 8 or 9 years, children spontaneously enact elementary planning activities and monitoring for mistakes that catch the eye. In the forthcoming years, planning and monitoring become more fine-tuned, and the metacognitive repertoire is extended with orientation activities, such as goal setting. It takes until 14 years of age before explicit evaluation at the end of the task is regularly displayed. Skills for reflection develop even later in adolescence. These developmental features impose constraints on the training of metacognitive skills. One should not expect the instruction of skills that emerge later in development, such as evaluation or reflection, to be successful in younger children.

Studies have provided evidence for a developmental increment of metacognitive skills. When presented with a series of inductive learning tasks, students in the age of 9, 11, 14, and 22 revealed an impressive growth in metacognitive skillfulness over the years (Veenman et al., 2004). Additional evidence in favor of metacognitive skill development has been obtained in longitudinal studies where students were followed for several years (Alexander et al., 1995; Van der Stel and Veenman, 2010). Despite developmental growth, a huge variation of metacognitive skillfulness within same-age students accounted for individual differences in learning performance (Veenman et al., 2004). The implication is that some students lag behind all along the developmental track.

Domain-Specific vs General Metacognitive Skills

Along the developmental trajectory, metacognitive skills evolve from being domain specific into being general by nature. At the age of 12 or 13, metacognitive skills are domain specific to a certain extent. Based on their study of students of 12 and 14 years of age, Veenman and Spaans (2005) argued that "metacognitive skills may initially develop on separate islands of tasks and domains that are very much alike," such as reading tasks vs problem-solving tasks. At the age of 14, however, metacognitive skills become an integrated, generalized repertoire of self-instructions that is applicable to a variety of tasks and domains, including novel ones (Van der Stel and Veenman, 2010; Veenman and Spaans, 2005; Veenman et al., 2004). This generality of metacognitive skills at the age of 14 has pertinent consequences for instruction and training. Metacognitive skills should be taught across tasks and school disciplines, so as to ensure transfer of skilled performance beyond the borders of a specific task or domain (Salomon and Perkins, 1989).

Assessment of Metacognitive Skills

Before teaching metacognitive skills, one needs to distinguish students with poor metacognitive skills from those with adequate skills. Instruction and training should focus on students with metacognitive deficiencies, rather than interfering with the smooth mastery of metacognitive skills in successful students. Two broad categories of instruments for assessing metacognitive skills pertain to *off-line* instruments, which are administered either prior or retrospective to task performance, and *online* instruments that are administered during actual task performance (Veenman et al., 2006). The essential difference between off-line and online instruments is that off-line methods merely rely on self-reports from the student, whereas online methods concern the coding of student behavior on externally defined criteria.

Off-Line Assessments

Off-line methods refer to questionnaires (e.g., Motivated Strategies for Learning Questionnaire (MSLQ) by Pintrich; Metacognitive Awareness Inventory by Schraw) and interviews. Off-line methods address students with questions about (the frequency of) their metacognitive strategy use and skill application. For instance, an item from the self-regulation scale of the MSLQ (Pintrich and De Groot, 1990) is: "I work on practice exercises and answer end of chapter questions even when I don't have to." Answers are given on a Likert scale, ranging from 1 ('not at all true to me') to 7 ('very true to me'). In interviews, similar questions are reframed as open-ended questions. When administered separate from performance on a target task, questions are formulated in terms of what students would do in general, or indicated as such during test instructions. The formulation of retrospective questions, on the other hand, refers to the specific task that was just completed.

The advantage of using questionnaires is that they can be easily administered to large groups of respondents, which obviously is the main reason for the omnipresence of questionnaires in metacognition research (Dinsmore et al., 2008; Veenman, 2005). Interviews have the disadvantage that they have to be individually administered and processed.

All off-line methods rely on self-reports by students, which entail major validity problems (Veenman, 2005, 2011). Students have to reconstruct their earlier metacognitive behavior from memory that makes their self-reports vulnerable to memory failure and distortions. Reconstructive interpretations may be elicited along with, or instead of correct recollections after task performance. Memory accuracy may be further distorted when off-line assessments are administered separate from actual task performance as students have to rely on their recollections of earlier learning experiences, further down the past. Another drawback of off-line methods is that questioning may interfere with the spontaneous self-report of metacognitive skills by students. Questions may prompt the recall of metacognitive behavior that never occurred. Not only may students be inclined to give socially desirable answers, they may also be triggered by questions to label their behavior accordingly. Students may take, for instance, their paraphrasing for summarizing.

Indeed, studies with a multimethod design have shown that different off-line measures often correlate poorly with one another, although they intend to assess the same metacognitive skills (Veenman, 2005). Furthermore, off-line measures hardly correlate with online measures obtained during task performance. Apparently, students do not actually enact what they have said beforehand, nor do they accurately recollect what they have recently done. In conclusion, off-line self-reports do not accurately reflect students' metacognitive skills because students cannot objectively review their own metacognitive behavior.

Online Assessments

Two frequently used online assessment methods are the analysis of think-aloud protocols and systematical observation. When thinking aloud, students are asked to merely verbalize their ongoing thoughts during task performance. Whenever they fall silent, students are encouraged to 'keep on thinking aloud' by the experimenter. Students are not incited to interpret their behavior, contrary to introspection. In fact, thinking aloud captures the content of working memory during task performance. Think-aloud protocols are recorded on tape and transcribed verbatim. In systematical observation, the student's task performance is video taped. Thus, observation protocols contain both behavioral information, as well as verbal utterings of students. Both think-aloud and observation protocols are rated by 'blind' judges according to specified criteria in a codebook. The application of such a standardized coding system by external agencies circumvents the validity problems mentioned before (Veenman, 2011). Moreover, the use of multiple judges allows for establishing an interrater reliability, indicating the rigor of a coding system.

Both methods of thinking aloud and systematical observation are time consuming. They need to be individually administered to students and the judgmental processing of data is labor intensive. Moreover, thinking aloud may not be appropriate to very young students with limited verbal capacities, or to tasks that are extremely difficult or demanding. Think-aloud protocols are then likely to be incomplete, which is known as the 'tip-of-the-iceberg' phenomenon (Veenman, 2011).

More recently, computerized assessments of metacognitive skills have become available (Veenman, 2013b; Veenman et al., 2014; Winne, 2010). A learning task is presented on a computer and all student activities in this computerized environment, such as button presses, scrolling, and electronic notes, are registered in a logfile on the computer. Frequencies and patterns of activities may be automatically computed and recorded as well. Logfile measures, however, represent activities of students on the cognitive object level without the metacognitive considerations provided by students when thinking aloud. A logfile indicates that a student scrolled back in an electronic text or pushed a particular button, but it does not disclose the reasons for why the student decided to do so. In order to determine whether logged activities are the consequence of control activities from the meta level, computerized assessments need to be initially validated against other online methods (Veenman, 2013b). Thus, computerized assessments should be able to distinguish between, for instance, button presses that occur at random and those deliberately chosen to pursue a particular metacognitive

goal. Once validated, computerized assessments can be administered to students at any time or place in a flexible way, or even to large groups of students at the same time (Veenman et al., 2014).

Studies with a multimethod design reveal substantial correlations among online measurements, indicating that different online methods converge in their assessments of metacognitive skills (Veenman, 2005). Moreover, online measures appear to be strong predictors of learning performance, in contrast with offline measures. These are compelling arguments for resorting to online methods when assessing metacognitive skills.

Instruction and Training of Metacognitive Skills

Students with learning disabilities or limited intellectual resources may suffer from metacognitive deficiencies (Pressley and Gaskins, 2006). However, many regular secondary school students and even intellectually gifted students may equally exhibit poor metacognitive behavior. Metacognitive skills can be successfully instructed and trained in all students (Dignath and Büttner, 2008). Like the acquisition of any other skill, however, it will take students' time and effort to arrange self-instructions in an organized set in order to attain a proficient level of skill application.

Three Principles for Instruction and Training

There are three principles for effective instruction and training of metacognitive skills (Veenman, 2013a). Any metacognitive instruction should abide by these three principles for successfully establishing a repertoire of metacognitive self-instructions in students.

Embedded Instruction

According to the first principle, metacognitive instruction should be embedded in a concrete learning context. Metacognitive skills cannot be executed in a 'void,' as they have to be operated upon cognitive processes at the object level. Embedded instruction enables the student to associate the conditional knowledge of *which* metacognitive skill is required *when* during task performance with the specific characteristics of the task. Metaphorically speaking, a learning context gives hands and feet to the metacognitive instruction of what to do when. Studies that failed to embed metacognitive instruction in a learning context invariably lacked training effects. In the same vein, study-skill lessons on school are fruitless if they are isolated from teaching content (Veenman, 2013a).

Informed Instruction

The second principle insists that students should be informed about the usefulness and benefits of metacognitive skills. When students are deficient in utilizing metacognitive skills, the execution of instructed skills initially requires extra effort and occupies working-memory space. This may result in a temporary cognitive overload of working memory, especially when the task at hand is demanding. In fact, task performance may be temporarily impeded by the effort expenditure needed for skill acquisition. Consequently, students may be inclined to abandon the instructed skills, unless they appreciate *why* the application of metacognitive skills facilitates their task performance in the end (Veenman, 2013a).

Prolonged Training

Following the third principle, metacognitive training should be spread over an extended period of time in order to allow for smooth and maintained application of metacognitive skills. When complex skills need to be built up from scratch, extensive modeling and practice of conditional and operational knowledge is required. When students are about to master a strategy, its execution still depends on conscious effort. Only after sufficient practice, the strategy is converted into a skill, that is, it becomes fluent and less demanding in its application (Veenman, 2013a). Duration of training, however, is not fixed. The time needed for metacognitive instruction and training depends on the quantity and complexity of skills that need to be acquired.

WWW&H Rule

The *WWW&H* rule (what to do, when, why, and how) captures the content of complete instruction of metacognitive skills in a given task context (Veenman et al., 2006). The four keywords of *what*, *when*, *why*, and *how* serve as the landmarks of adequate metacognitive functioning. Explicit instruction of *WWW&H* is crucial to students for linking task settings, which provide the conditions for action, to potential metacognitive actions in the initial phase of skill acquisition (Gollwitzer and Schaal, 1998; Veenman, 2011). For instance, when instructing students to apply comprehension monitoring during text studying, students should be explicitly taught what comprehension monitoring is ('checking your understanding of words and phrases'), when monitoring should be applied ('in case of misreading, or after each paragraph'), and why monitoring is necessary ('lack of understanding corrupts further reading'). Through modeling and scaffolding, the teacher facilitates the acquisition of monitoring processes in students. The teacher first demonstrates the *WWW&H* rule to the student while reading aloud a particular text. Next, the student enacts the monitoring skill, while receiving feedback from the teacher. Through further practice, the student should accomplish fluent mastery of the *WWW&H* rule.

When teaching multiple metacognitive skills, often step-by-step action plans are used that prescribe the order of metacognitive activities (Veenman, 2013a). Each step describes a concrete action, rather than an abstract skill. For instance, when solving science problems, orientation skills are represented by subsequent steps for reading the entire problem statement, discerning relevant from irrelevant information, making a sketch of the problem situation, determining what is given and what is asked for, and estimating the outcome. Such step-by-step action plans help students to integrate conditional knowledge with the actual enactment of skills in order to build up a repertoire of metacognitive self-instructions.

Metacognitive Training: An Example

Pressley and Gaskins (2006) designed a particularly successful training program at a special school for students with very low reading abilities. Throughout each school day, all teachers across disciplines incessantly addressed the students with metacognitive reading instructions, such as establishing a goal for reading, identifying the theme and main ideas in a text, relating new information to prior knowledge, monitoring understanding through self-questioning, dealing with incomprehension by rereading or looking for additional information sources, and summarizing the main conclusions. Instruction explicitly addressed when, why, and how strategies were to be used. After spending several years at this special school, most students returned to regular education with above-average scores on a national reading test. Similarly effective programs with step-by-step action plans are the IMPROVE program for solving math problems (Kramarski and Mevarech, 2003), or Systematical Approach for solving physics problems (Mettes et al., 1981).

Availability vs Production Deficiencies

Even though students may exhibit equally poor metacognitive behavior, they may differ in what causes their poor behavior. Students may suffer from either an availability deficiency or a production deficiency (Veenman et al., 2000). Students with an availability deficiency do not have metacognitive skills at their disposal, whereas students with a production deficiency are obstructed in the execution of available skills. Both deficiencies require differential approaches in the instruction of metacognitive skills.

Availability Deficiency

Students with an availability deficiency lack the essential metacognitive knowledge, the appropriate skills, or both as a rule. Take planning as an example. Students may not be aware of what planning is, when planning is required, or why planning is worthwhile. Even when this conditional knowledge is available, still students may not know how to do planning. For instance, they may not be able to transform an abstract goal into concrete subgoals with an orderly sequence of activities. Merely urging students to plan their work, as teachers do from time to time, does not help students to surmount an availability deficiency. Students, who are devoid of metacognitive skills, need to be instructed and trained from scratch, that is, fully instructed and modeled according to the three instructional principles and the *WWW&H* rule.

Production Deficiency

Students with a production deficiency are capable of skillful behavior under familiar conditions, but for some reason they do not spontaneously execute the available skills in a particular learning situation. For instance, they do not know when to plan or monitor their actions in the context of a specific task, they do not recognize the relevance of those skills for that particular task, or test anxiety may interfere with the deployment of skills. These students need not be fully trained in *how* to apply metacognitive skills. They merely should be reminded of applying the necessary skills by providing them with metacognitive cues during task performance (e.g., 'now is the time to draw up a plan'). A remedial teacher could deliver these cues or students could autonomously handle a set of cards on which the subsequent steps of an action plan are printed (Veenman, 2013a). Computerized learning environments could also provide individualized prompts that respond to (omitted) student actions on the computer (Veenman, 2013b; Winne, 2010). A key feature of cuing or prompting is that skills are not further instructed or modeled. Extended instruction and training could even interfere with common mastery by students with a production deficiency.

So far, the only valid method for distinguishing students with availability vs production deficiencies is to provide students with metacognitive cues during task performance (Veenman et al., 2000). Students are evidently suffering from a production deficiency when metacognitive cuing results in enhanced metacognitive behavior and learning performance. Additional cuing should suffice for these students, until they prevail over their production deficiency. Students who do not respond to cuing, on the other hand, are *assumed* to suffer from an availability deficiency. Most of them actually are available deficient, but others may have been insusceptible to the metacognitive cues given. When submitting these alleged available-deficient students to ample metacognitive instruction and training, instructors should be aware of this limitation. One student may pick up metacognitive instructions more rapidly than others, which requires a flexible approach by the instructor.

Conclusion

Effective metacognition is characterized by the application of metacognitive conditional knowledge, by knowing how to execute metacognitive skills, and by understanding the benefits of using those skills. Students should incorporate these principles of adequate metacognitive functioning in an organized set of self-instructions. Not all students, however, spontaneously develop such a general repertoire of metacognitive skills. Depending on whether conditional or operational knowledge is missing, metacognitive-deficient students should either be cued, or fully trained to enact metacognitive skills according to the three instructional principles and the *WWW&H* rule. Eventually, students should master a repertoire of metacognitive self-instructions that is broadly applicable to any new learning situation.

Abstract

Teams are essential in order to handle the complex problems faced by the contemporary organization. Consequently, a deeper understanding of what makes a team effective has been an ongoing goal of researchers. However, our understanding of effective teams is capped by the quality of measurement used to assess them. This article first provides theoretical basis for understanding the measurement of teams. Based on this information, we further offer guidelines and recommendations for those seeking measure team dynamics.

Introduction

The ever-increasing demands of the modern day organization are, at times, too much for an individual to handle. Contemporary technologies have increased the speed, the amount, and the variety of information organizations are expected to process. A consequence of this growth has been the increased use of teams as an appropriate means for handling complex problems and issues above and beyond individual capacities. As the research on teams have accumulated over the past 30 years – and the use of teams in organizational settings show no signs of slowing down – this article aims to fortify the assessment of teams in organizational settings by focusing on the measurement aspect of teamwork. Specifically, we highlight the importance of having a complete team measurement system, as a common issue arising during team assessment is the deficient measurement of multiple team components. A complete team measurement system gauges the individual characteristics of the team (e.g., knowledge, skills, abilities, and other characteristics), both taskwork and teamwork processes/emergent states (e.g., communication, collaboration, cohesion, conflict), and team outcomes. This article will briefly review a representative sample of what is known about each of these team measurement system components. First, we define teams and elaborate on these three components. Next, we identify six considerations for those developing/selecting team measurement systems. Third, we feature a representative sample of methods and tools that can be used in such systems. Finally, we end with a few remarks about the next frontier in teamwork and its measurement.

Overview of Team Measurement Systems

For our purposes, we define teams as a distinguishable set of two or more individuals who must perform distinct, complementary, or interdependent tasks en route to accomplishing a shared, common goal (Salas et al., 1992). This particular definition lends itself well to the discussion of team measurement systems. In the broadest of terms, a system of team measurement could reflect any battery of techniques used to observe and measure teams. However, a team measurement system is not complete unless it captures the individual characteristics of teams, team processes and emergent states, and team outcomes. One way to think of such systems is through the model displayed in **Figure 1**. This figure depicts two different levels of specification (i.e., individual level and team level) and three different components (i.e., inputs, mediators, and outcomes). In order to have a complete system, it is necessary to measure components in all six sections of the model. Though the measurement of individual-level factors is important, this article will focus on the measurement of team-level factors. In the following section, we will briefly define and discuss each of these team-level components.

Inputs

A team is made up of a collection of individuals whereby each individual has certain knowledge, skills, abilities, and other characteristics that have the potential to affect the work they do while on that team (Barrick et al., 1998). Research has indicated the importance of different types of knowledge (e.g., task knowledge), skills (e.g., technical skills), abilities (e.g., cognitive ability), and other (e.g., personality) characteristics in terms of their impact on performance at an individual level (Bunderson and Sutcliffe, 2003; Carson et al., 2007; Driskell et al., 2006; Earley and Mosakwoski, 2000). However, it has been suggested that the KSAOs related to team effectiveness may differ than those that are effective at the individual level (Morgeson et al., 2005). For instance, Stevens and Campion, (1994) suggest that rather than focusing on more individual-level KSAOs (e.g., technical skills, personality traits), there are specific interpersonal KSAs (e.g., conflict resolution, collaborative problem solving, and communication KSAs) and self-management KSAs (e.g., goal setting and performance management and planning/task coordination KSAs) that are more applicable to understanding teamwork. Other critical team-level input factors include, but are not limited to, social skills, teamwork knowledge, expertise diversity, task interdependence, and leadership skills (Morgeson et al., 2005; Chen et al., 2004; Burke et al., 2006; Mathieu et al., 2008).

Mediators

Mediators of the input–outcome relationship in regards to teamwork refer to those processes and other variables that serve

Figure 1 Multi-level team measurement system model. Solid arrows represent a stronger association between components. Dashed lines represent a weaker association between components. Influenced by McGrath, J.E. 1964. Social psychology: A brief introduction, New York, Holt, Rinehart, & Winston; Ilgen, D.R., Hollenbeck, J.R., Johnson, M., Jundt, D., 2005. Teams in organizations: from Input-Process-Output models to IMOI models, Annual Review of Psychology 56, 517–543; and Mathieu, J., Maynard, M., Rapp, T., Gilson, L., 2008. Team effectiveness 1997–2007: a review of recent advancements and a glimpse into the future. Journal of Management 34 (3), 410–476.

as the mechanisms through which individual and team level inputs influence team outcomes (Ilgen et al., 2005). When selecting important team-level mediators, there are two important distinctions to make. First is the difference between taskwork and teamwork. Taskwork is comprised of the actions that team members perform, which are not dependent on any of their fellow team members, whereas teamwork is comprised of those actions made necessary by interdependence and are used to facilitate coordination (Salas et al., 2008). From a measurement standpoint, one could consider actions that represent taskwork to be specific to the individual (e.g., behaviors an individual engages in to complete the team's goal), whereas teamwork needs to be measured at the team level (e.g., interactions between team members). Thus, the focus of team-level measurement is on teamwork mediators.

The second distinction regarding mediators relates to the different types of teamwork. Teamwork can be separated into two different classifications: processes and emergent states. Teamwork processes are the observable behaviors that occur when team members interact with one another, whereas emergent states are cognitive, motivational, and affective states of the team (Marks et al., 2001). Research has demonstrated that both team processes (e.g., strategy formulation and planning, mission analysis, affect management) and emergent states (e.g., team mental models, team cohesion, team empowerment) are crucial predictors of team performance (Edwards et al., 2006; Lepine et al., 2008; Smith-Jentsch et al., 2005).

Outcomes

Team outcomes can be separated into two distinct sets: performance and affective outcomes (Hackman and Morris, 1975). Team performance outcomes are typically denoted by the assessment of the team's accomplishment of assigned goals. The measurement of these outcomes can range from a simple checklist of predefined goals the team was assigned to accomplish to a supervisor's assessment of a team's accuracy and quality of work performed. The assessment of team performance outcomes typically is directly related to the accomplishment of task/team goals. Conversely, affective outcomes target how the team feels regarding their teamwork experience. Some prominent affective outcomes include the team's willingness to work together in the future, team satisfaction, and team member trust. Though some may consider affective outcomes are less important than performance outcomes, they may have critical implications for teams that plan to perform together in the future.

As mentioned earlier, this section served to briefly review some of the more prominent team-level factors crucial in the selection or development of any team measurement system. There are several other factors that are not represented here, but still may be needed in a system depending on the needs of the organization and context of the team. However, the selection of constructs is not the only consideration one should make in developing a team measurement system. In fact, the selection of these constructs is largely influenced by the purpose driving the need for measurement. The next section covers the significant considerations that we believe are necessary in the development or selection of any team measurement system.

Team Measurement System Selection/Development Considerations

Measurement is paramount for the understanding of human behaviors (Meister, 1985). This argument can be extrapolated to all levels of human behavior, an individual as well as a team. Therefore, as the development and use of a team measurement system is vital to understanding intricacies of an effective team, some basic assumptions should be covered regarding the development of such systems (Table 1). These assumptions form the basis for the design, development, and testing of team measurement systems. Understanding these underlying assumptions leads to the recognition that there are certain requirements that underlie effective measurement. This section outlines six different considerations that organizations and practitioners should contemplate when developing/selecting a system of measurement for teams. While developing/selecting a team measurement system, it is vital to recognize that

Table 1 Representative sample of basic team measurement assumptions

Basic measurement assumptions
1. The construction of team measures must be based on team-based theoretical models.
2. Team performance and processes are reflected through the actions and observable outcomes of individual team members
3. The goal of measurement is to allow observations of behavior and changes in behavior of team members, which represent underlying processes.
4. Certain team processes and outcomes are more readily available for measurement than others.
5. Processes not easily measured must be matched to corresponding observable behavior or quantified through feedback from team members.
6. Individual performance of team members can be considered within the context of the team and used, in combination with others factors, to assess team performance.

Based on Meister, D., 1985. Behavioral Analysis and Measurement Methods, Wiley-Interscience; Brannick, M.T., Salas, E., Prince, C.W., 1997. Team performance assessment and measurement: theory, methods, and applications, Psychology Press.

these considerations are not independent of one another and therefore should be deliberated in their entirety.

Measurement Purpose

The first consideration facing those who are developing or selecting a team measurement system is to specify the purpose of the measurement. Team measurement systems can be used to serve many purposes, such as team member selection, training feedback, performance evaluation, and promotion. The selection of the purpose will guide measurement content selection, decisions regarding the type of data needed, and appropriate data collection resources (Mesiter, 1985). For instance, if the purpose of the measurement is simply to gauge team members' reactions to training program, a paper-pencil measure specifically targeting their feelings about the training may suffice. However, if the purpose of the measurement is to provide feedback and develop a flight crew, a more labor-intensive, complex system may be necessary. In this latter instance, critical team process constructs would need to be specified, measured, and tied to specific team outcome variables so that detailed feedback could be given regarding the team's performance. Therefore, specifying the purpose of the measure is a critical first step in any team measurement system.

Construct Selection

Once the purpose of the team measurement system is specified, the next step involves selecting the constructs of interest. It is important for developers to measure all three factors previously discussed: team-level inputs, mediators, and outcomes. Incorporating all three elements into a team level system of measurement will provide the most holistic understanding of what factors may be impacting team performance, and how such factors may be interacting with one another. If the decision is made to only select a portion of these factors, the team measurement system may be deficient and unable to accomplish the overall purpose. For instance, only measuring team performance outcomes in a training program would not be conducive to providing feedback to team members, a critical aspect to effective training. In order to provide feedback, specific team processes must be measured. By giving feedback on specific team processes, team members will be able to learn specifically how they were performing improperly. Additionally, the selection of constructs identified as inputs, mediators, and outcomes will also impact when these constructs should be measured, as will further be elaborated upon later in this article.

Measure Referent

When measuring team-level variables, it is imperative that those developing measures understand the implications associated with specifying the focal point or referent of the measure. The focal point or referent of the measure refers to whom or what the measure is attempting to obtain information about; for teams, this could be regarding the entire team as a whole, or it could refer to the individuals of the team (Chan, 1998). This consideration encapsulates several questions: Do external raters need to observe the construct or can the construct be assessed through paper–pencil measures? Are the items on the measure specifically referring to the team instead of the individual? If the items on a measure are referring to the individual, can they simply be aggregated to a team level or is a more complex aggregation technique needed? Is the targeted construct observable? Does the task provide the opportunity for the targeted-construct to be performed? Such questions are critical to ask in order to ensure that the appropriate focal point is utilized for each of the constructs to be measured.

The relevance of these questions is partially determined by the constructs selected. For instance, when assessing team cohesion, it may be necessary to utilize survey items that specifically use the team as referent. Given that team cohesion is an emergent state, which can be very challenging to observe by outsiders (Mathieu et al., 2008), having team members report on their feelings with the team as the referent should provide the most appropriate measure of the construct. Alternatively, if one decides to measure teamwork processes, it may behoove the measurement system designer to choose a situation in which team members would have the opportunity to perform the behaviors associated with the construct prior to measurement in order to ensure that those behaviors have a chance to emerge at the team level. Much like the previous considerations, the decisions made here greatly influences the choices available in the forthcoming steps.

Measurement Source

There are five primary measurement sources typically used in team measurement systems: team members, supervisors, trained raters, customers, and objective sources. Not all of these sources are equally effective in assessing all different factors (i.e., inputs, mediators, and outcomes). For example, the measurement of input factors is more accurate when coming from the team members themselves. Supervisors may not be as accurate at assessing these input factors as they may not be aware of each team members' expertise. A summary of the specific advantages and disadvantages for each source is

Table 2 Pros and cons of measurement sources

Measurement source	*Pros*	*Cons*
Team members	● Observed team members on a daily basis ● Good understanding of what should be done ● Can access their own cognitions	● May be too lenient on team members if team rewards are tied to team behavior ● May be too severe on ratings if the climate is very competitive
Supervisors	● Expert understanding of what constitutes good behavior ● Witness to best behaviors	● May not be around on a daily basis ● Cannot assess team cognitions
Trained raters	● Trained understanding of the behaviors being assessed ● May be experienced in doing ratings	● Not privy to day-to-day operations ● Not familiar with organization/team culture
Customers	● Gives a different perspective compared to the aforementioned sources. ● Ratings come form experience with the team	● Ratings are very heavily influenced by experience ● Does not have an understanding of what constitutes good performance.
Objective sources	● Removes a great deal of bias from team measures. ● Can be concretely defined by the researcher	● Can only measure what it is programmed to measure ● Can typically only measure simple things (e.g., frequency, counts)

provided in Table 2. One must be selective in choosing the source of the measure. As some sources are better at assessing certain factors than others, the inappropriate selection of measurement source could result in inaccurate/biased measurement, which would consequentially lead to improper assumptions made about the team. Thus, it is highly recommended to use multiple sources in collecting team data. Some have even argued that it takes a team to effectively measure a team (Dickinson and McIntyre, 1997).

Measurement Timing

The fact that teams develop and evolve over time has implications on when constructs can and should be measured (Kozlowski and Klein, 2000). Certain constructs may be more appropriate to measure during certain points in a team's performance cycle than others. For instance, teamwork processes targeted at setting up teams for successful performance, such as mission analysis, goal specification, and strategy formulation and planning, may be more observable during the initial stages of team performance. Additionally, the choice of source may have implications on when a construct is measured. For example, externally trained raters can only make judgments regarding targeted constructs while the team is performing. Other team factors should only be measured at the end of team performance (e.g., objective performance, affective outcomes). Additionally, the timing of when constructs are measured may also be influenced by environmental characteristics that are not under the control of the team measurement system designer. If, for example, one of the conditions set forth by a union is that team member can only fill out research surveys when they are clocked in, the developer must try and create a measure that team members can fill out without disrupting the constructs they are trying to assess.

Measure Validation

The last consideration concerns the validation of the measures within a team measurement system. Depending on whether one is selecting or developing the measures in a system, these considerations will change slightly. However, the assurance that these measures have undergone proper validation processes is one of the most crucial steps in the development/selection of a team measurement system. Simply put, validity concerns whether the measure actually captures what it is supposed to measure (Messick, 1980). Though validity can never be absolutely proven, evidence can be provided supporting a measure's validity. There are three main types of validity used to support a measure's credibility: content validity, construct validity, and criterion-related validity. Each of these provides different types of evidence of validity and, consequently, one should look to support all three validity types.

Content validity typically refers to the extent that a measure represents a construct in its entirety. One way to provide evidence for content validity is by using subject matter experts (SMEs) to review a measure for any construct deficiency or contamination. Support for a measure's content validity does not necessarily have to come through an empirical process. That is, support for content validity can be established through a rationalized process of judgments rather than a quantitative investigation. Criterion-related validity simply concerns the degree to which a measure predicts an outcome of interest. Evidence for this type of validity is established when a measure correlates with the criterion. That is, criterion-related validity evidence is typically represented in the form of a correlation coefficient between a measure (predictor) and a criterion. Lastly, construct validity concerns whether or not a measure quantitatively represents the construct that it is designed to represent. There are several ways one can establish construct validity such as creating a nomological network or creating a multi-trait multi-method matrix (Cronbach and Meehl, 1955; Campbell and Fiske, 1959). Each type of validity is critical to the credibility of a team measurement system. As such, providing evidence for each type of validity is a fundamental consideration.

Available Measurement Tools

During the creation of a team measurement system, it is not necessary to 'reinvent the wheel,' or start completely from scratch in terms of developing tools. There are several tools/methods available to assess a team's inputs, mediators, and outcomes. In this section, we cover a representative sample of some of these tools/methods used to measure teams including rating scales, behaviorally anchored rating scales (BARS), event-based measurement scales, automated performance measurement, concept mapping, pathfinder, and probed protocol

analysis. There are numerous cases in recent literature that demonstrate the applicability of these tools for the collection of team data (Jones and Harrison, 1996; Lynn and Reilly, 2000). Moreover, though many of these tools can be used as a combination of inputs, mediators, and outputs, some are more apt at assessing certain constructs than others.

Rating Scales

One of the most common forms of assessment of team constructs is rating scales. Rating scales ask people to indicate their attitudes, opinions, beliefs, or feelings on a large number of items. Thus, rating scales can be used to assess reflections of team behaviors, opinions concerning how team members feel, or even beliefs concerning team member's cognitions. There are a number of ways to develop rating scales. If one desires to gauge opinions concerning team members' behavior, the first step would be to compile a description of the behaviors of interest. One approach to identifying and accumulating these behaviors would be to use a critical incident technique. A critical incident technique gathers information from SMEs regarding memorable events, both positive and negative, which occurred in a specific situation (Chell, 1998). These behaviors would then serve as the content for the questions being asked on the measure.

Once the content has been identified, there are several options on how to present the information. A few possibilities include: (1) scale points can simply be reflected by numbers, (2) descriptive words can be used at end scale points, or (3) verbal descriptions can be used at each scale point (Meister, 1985). Another choice comes with deciding how many scale points to be used. First, there must be enough scale points to fully represent the question being asked as a dichotomous scale might not represent the different degrees of the attribute being assessed. Another consideration is whether to use an odd number of scale points, which provides the rater with the option of choosing a neutral response. These options have their respective pros and cons, and it is completely up to the measure designer which option they prefer. An example of a ratings scale is provided in **Figure 2**.

Behaviorally Anchored Ratings Scales

BARS are a type of rating scale first introduced by Smith and Kendall (1963). Much like rating scales, BARS use verbal descriptors at each scale point. However, unlike rating scales, BARS provide very specific behavioral descriptors at each scale point. These anchors provide more concrete examples of what behaviors represent each scale point. That is, rather than one word representing each scale point (e.g., agree, never, always, disagree), BARS scale points has specific behavioral descriptions. Consequently, this approach lends itself well to the critical incident technique mentioned above. Instead of the behaviors becoming part of the item text (as alluded to above), they are transposed onto the scale points. Furthermore, BARS are especially suitable for assessing team behaviors. One distinct advantage of BARS over traditional rating scales is that it helps control for any individual idiosyncrasies of the raters (Salas et al., 2003). An example is provided in **Figure 3**.

Event-Based Measurement Scales

Another behaviorally oriented approach to team measure is the event-based measurement scales. Using this approach, the measure designer first identifies the team competencies they wish to measure. Following this, they insert events into behavioral scenarios designed to cue the specific behavioral competencies. In doing so, practitioners can tie measurement directly back to the targeted competences. Furthermore, this approach does provide some ease for raters. That is, since the raters know what cues are embedded into the scenario and when these cues take place, they are better able to focus on a certain behavioral competency when the time arises. By creating a situation in which team behavioral ratings are consistently drawn from the same event across teams, event-based measurement scales typically contain exceptional psychometric properties. An example of this type of measurement approach is provided in **Figure 4**.

Automated Performance Measurement

The type of information that automated performance measurement tools can collect is tremendously diverse. Automated performance measurement tools have the ability to collect data as simple as automatically counting the number of times team members say a certain word to data gathered from a highly complex jet flight simulator. One of the advantages of automated performance measurement tools is that they, to a certain degree, remove the errors associated with human decision making. Further, tools like this are not as intrusive as other aforementioned approaches. However, there are several downsides of using an automated performance measurement tool. First, they can be extremely expensive to design and maintain. Next, automated performance measures can only measure what it was programmed to measure. If you want to measure something else, you might not be able to get this information from data that you have already collected. Another

Question: How often did the team members offer information on other team members' performances?

Figure 2 Example of a rating scale measuring feedback.

Question: How effective were team members in providing feedback?

Figure 3 Example of a behavioral anchored ratings scale measuring feedback.

Flight segment	Event	Target	Hit
Approaching checkpoint	Navigation	Report distance to checkpoint.	
		Report outbound heading from checkpoint.	
At checkpoint	COMMUNICATION from base: SIGMET (SIGnificant METeorlogical information) over checkpoint.	Note implications of SIGMET (e.g., cannot land at checkpoint).	
		Obtain additional information (e.g., from flight service).	
		Make new plan – choose alternates from: • Return to base (best choice) • Pleasanton • Kelly AFB • Randolph AFB	

Figure 4 Events and associated TARGETS for a short-hop segment in which helicopter crew is on a training maneuver (Fowlkes et al., 1994).

downside is that it can only detect overt responses (Meister, 1985). Additionally, these types of tools are not especially well designed at measure team attitudes or cognitions.

Concept Mapping

Concept mapping produces a graphical representation of the knowledge content and structure of an individual (Swan, 1995). Concept mapping has more recently been adapted from the individual level to assess team cognitions. This method creates a map of cognitive concepts that are linked together based on their association with the other concepts. In order to generate the concept maps, the researcher can request the data from team members through interviews/surveys or by post-hoc examination of the data (Mohammed et al., 2000). There are several variations of concept maps, all with their unique purpose. For example, Pathfinder elicits similarity judgments from team members to produce a representation of the team's concept structure (Mohammed et al., 2000). This technique involves the researcher coming up with predefined concepts, usually using

a team task analysis. Participants are then instructed to make pairwise comparison ratings on each concept pairing. After these paired-comparison ratings are made, Pathfinder uses a specialized algorithm to determine the psychological proximity of the concepts as well as a conceptual structure (see Goldsmith and Kraiger, 1997; Cooke and Schvanevedlt, 1988).

Summary

Certain measurement tools are more apt at assessing attitudes (e.g., rating scales), behaviors (e.g., BARS, event-based measurement scales), and cognitions (e.g., concept mapping). When selecting measure to use in a team measurement system, it is recommended that one considers the strengths and weaknesses of each of these measurement tools. Though we emphasize the importance of having a complete team measurement system, if the proper tools are not utilized in appropriate ways, having such a system is meaningless.

The Future of Team Measurement

While much has been discussed thus far regarding the current state of the science of team measurement in terms of important considerations and potential approaches, there is still much to be done. Team measurement as a science is far from being perfect, especially as we continue to explore new and changing team contexts. The following provides a brief summary of two particularly important areas requiring future research, the increasing use of distributed teams communicating via virtual media, and the need to better represent the dynamic and temporal nature of teamwork.

Distributed Virtual Teams

The growing implementation of teams whose members are geographically distributed and communicated virtually is also an issue in need of additional research. Distribution of team members has become commonplace in organizations around the world as a means to deal with complex world problems, and is the focus of a growing body of academic research across multiple disciplines (Connaughton and Shuffler, 2007). Distributed virtual teams are defined as teams whose members are geographically separated and must utilize some type of technology in order to communicate, whether it be something as basic as e-mail or as complicated as a virtual (Driskell et al., 2003). This definition illustrates the major features of such teams: the use of technology to bring together team members that may be spatially distributed (i.e., not colocated), or temporally distributed (i.e., interacting asynchronously; Kozlowksi and Bell, 2003).

Distribution and virtuality are important factors to consider in terms of team measurement as they can change how team members interact with one another. Initial results of both lab and field research illustrate differences in distributed virtual teams when compared to face to face teams (Bos et al., 2006). However, these teams are often investigated using the traditional metric approaches applied to face-to-face teams, and do not take into consideration how distribution and virtuality may be influencing when and how metrics should be captured. Overall, the research regarding how to capture the nuances that may be important to distributed virtual teams is very limited, especially in terms of partial distribution as well as the combined influences of distribution and virtuality. Given the rise toward distributed teams relying upon technology to communicate, it is therefore critical that attention be paid to this issue from a measurement perspective.

Dynamic Assessment of Team Constructs

Although advances in measurement over recent years have led to increasingly effective techniques for capturing team level constructs, additional work is needed in order to effectively capture the dynamic nature of teams. The measurement techniques previously described in this article are effective, but do not always capture the degree to which teams can change rapidly over a period of time. For example, observers may only capture teamwork processes for a short period of time during the performance episode that they are observing, leaving out the richness of how the team may have developed up to that point or after that point. Furthermore, paper-based metrics provided by team members force members to summarize their thoughts and feelings over a period of time, essentially averaging rich data that could be critical to effectively understanding the nature of team performance. Thus, it is critical that future research regarding teamwork and team assessment focus on the dynamic, changing nature of teams over time.

Along these lines, increased attention regarding the implementation of unobtrusive measures in team settings has led to the proposed use of metrics such as physical closeness of team members over a period of time or biometric data (e.g., heart rate, perspiration, eye tracking) as proxies for team level constructs such as trust or cohesion (DeCostanza et al., 2012). Additionally, the need to reduce the reliance on expert observers is also critical to capturing this dynamic nature of teamwork. While metrics such as the BARS and TARGETS techniques described in this article allow less-expert observers to assess team variables, this still incorporates the use of humans in the measurement process, increasing the likelihood of error and mistranslation of information. Furthermore, such observers cannot be present constantly over the lifecycle of a team in every situation; therefore changes that the team may experience in the constructs of interest may not be fully captured. Thus, other ways to reduce this reliance on experts must be developed. In sum, team measurement is a critical concept for both research and practice, as only through effective measurement we will be able to more accurately understand the nuances of teamwork and team performance necessary for enhancing teams and their success in organizations.

Abstract

Technological change and its impact on work is explored within Emery's (1969) sociotechnical framework where changes in the technical system affect the cultural, social, and management fabric of organizations. The focus of this article is on the digital revolution, and its impact on employment practices, teams, and research opportunities in a global and culturally complex environment. Highlighted within this article are work relevant developments in areas such as robotics, the Internet, social media, and data analytics, all made possible through the abundance of computing and communication capacity. Areas for future research are outlined.

Each wave of technological change, including most recently the digital revolution, has had a major impact on the nature of work. This article highlights recent technological development and explores its impact on the social and cultural nature of work and organizations.

A useful framework for understanding the role of technology in work is Emery's (1969) sociotechnical systems model of organizations where the technological, social, and managerial components interact. The technological system includes all the equipment, infrastructure, and technology in the workplace. The social system includes cultural and other diverse groups and individuals, and the social processes and informal channels used to communicate and negotiate in the workplace. The managerial system is concerned with power and authority within the organization, including decision making and formal lines of communication. Technological change has an obvious and direct impact on the technical system but also on the social/cultural and management systems, especially in relation to modes of communicating and working, and the ways in which data are gathered, analyzed, and used.

Technological Change: Information Technology, the Internet, and the Digital Revolution

Each new wave of technological development has resulted in changes to the nature of work (Wilpert, 2000). Examples include the Industrial Revolution, developments in transport (air, land, and water), and most recently the information technology and communications revolution also known as the digital revolution. The uptake of new technologies has not been uniform across the globe, and it is therefore difficult to speak of this without acknowledging the diversity of stages of technological change in different countries and cultures.

Industrialization resulted in a particular form of work that emphasizes the division of labor, centralization of functions, and new forms of labor relations. The digital revolution has added another layer of change with implications for the location of work in time and space, and for the immediacy of communication irrespective of distance. Examples of the digital revolution include the abundance of computing capacity; the use of robots, smart devices, and sensors; and the rise of the Internet, video-based conferencing, social media, and smart phones in the home, in school, and at work.

Although computerization has been evident for decades, the recent growth in the sophistication, speed and availability of computing power, storage capacity, and communication bandwidth lies at the heart of the current digital revolution, providing the platform for developments in robotics and other areas that have and are radically changing work. As a consequence of faster and more economical computing and improvement in sensory capacity, planning control, actuation, and power systems, robots have become cheaper and more sophisticated (A Roadmap for US Robotics, 2009: pp. 17–19, 63–70, 74–78; Kozlowski, 2011). We illustrate the impact of recent digital advances using examples of robotic applications in manufacturing, transport and defense, while also highlighting the role of social robots, avatars, and the Internet in teamwork and other social roles.

Robots have been used for many decades on the factory floor to assist with the production of cars and other products and their impact is growing at 8% per year, representing a US $5 billion industry in manufacturing in 2009. Robots are seen to be important because of the aging population where optimistic forecasts point to two robot workers for each retired person by 2050, helping solve the need to sustain increases in productivity with a decrease in the number of human workers (A Roadmap for US Robotics, 2009: p. 9).

Robots are not only used in the manufacture of vehicles, but have led to the appearance of autonomous vehicles on highways and city roads (Dietsch, 2012). These are now being tested in traffic in the USA, demonstrating that they can move from one location to another without assistance of human beings. Autonomous vehicles also are expected to bestow many economic and social benefits with one being to transport those who are aged and/or handicapped and thereby provide sustained personal autonomy. This will be important with the expected doubling in the numbers of retirees as a percentage of the workforce by 2030 in countries such as the USA.

Robots have emerged as an important technology in the recent wars in Iraq and Afghanistan (Singer, 2009). Drones such as Predators, Global Hawks, and Ravens and mobile unmanned ground vehicles have replaced soldiers in performing some tasks especially those that are repetitive, dirty, distant, and dangerous such as mine clearance and bomb disposal.

In manufacturing, old school engineers who worked with lathes, drills, stamping presses, and molding machines have

been replaced by automated machines and robots with highly educated workers operating these via their computers. Three-dimensional printers can be used to build products layer by layer, allowing the manufacture of tailored products each customized to individual tastes and requirements (additive manufacturing). Factories are becoming vastly more efficient because of the digitization of manufacturing and the use of smart software (The Economist, 2012). Mass production is, in some areas, giving way to the production of tailored products, made economically in much smaller numbers and with less workers albeit highly skilled ones. These innovations are also influencing hospitals, schools, office buildings, and other places of work where smart technology is replacing workers in their traditional roles, and creating a range of new types of work.

These new technologies provide benefits such as reducing workplace accidents, shrinking manufacturing times, and leveraging the skills of human beings with robot strength, precision, and repeatability (Dietsch, 2012), but automation also creates challenges for the social and managerial systems as discussed later.

The Internet has revolutionized communication in organizations and society generally. Examples include the impact of Internet shopping on retailing, and the effect of e-mail and other electronic communication on traditional postal services. Secure digital mobile devices such as smart phones and tablets are becoming the mobile virtual offices of the future and are making it easier for people to communicate, cooperate, collaborate, and codesign (Gregg, 2011). Workers interact with others on the Internet to solve problems, tackle market opportunities and produce innovative products. Many organizations are also adopting social networking for marketing and other functions. Falls in technology costs and the digitizing of back-office functions such as clerical support and information technology services are expected to make virtual or 'bricks and mortar' organizations, smaller, leaner, and more efficient.

Technology has historically created more jobs than it has destroyed. Similarly the rise of the Internet displaced some jobs but continues to provide new ones from web site designers to professional bloggers (Pelissie du Rausas et al., 2011). However, it is likely that jobs requiring a 'high degree of flexibility in perception, motion and control that robots currently lack' (Chitta et al., 2012: p. 58) will not disappear in the short-term and hence nonroutine, low-paying jobs that are difficult to automate or outsource such as taxi drivers, hairdressers, and gardeners are likely to remain in demand.

Social, Cultural, and Managerial Systems

Organizations and workplaces are increasingly multicultural and diverse. This has arisen because of globalization of industry, education, and many other activities, and increased migration and portability of populations. Many large international firms have branches throughout the world, with a consequential requirement placed on their employees to deal with different ethnic groups (Hesketh and Bochner, 1994). These trends have led to the recognition of a need to understand different cultures as consumers and employees.

Triandis defines culture in terms of the group's characteristic way of perceiving its social environment (Triandis, 1972: p. 3). This should be extended to the group's way of perceiving the technological and managerial environment. Values are fundamental to these perceptions, and Smith and Schwartz (1997) have made a major contribution to thinking in the area through their empirically based typology for evaluating environments cross culturally. Cultures differ in terms of: (1) conservatism (collectivism), where the emphasis is on group goals, interdependence, and closely knit groups; (2) hierarchy, where resources and roles are allocated by the hierarchy; (3) mastery, where the emphasis is on self-enhancement and achievement; (4) autonomy (individualism), with independence emphasized in the pursuit of individual goals; (5) egalitarian commitment, where the welfare of others transcends self-interest; and (6) harmony, for the world as it is and for the preservation of the environment. Nations can be characterized in terms of distinct cultural value patterns or profiles that map on to a circumplex. Bochner and Hesketh (1994) present data that show how these types of value differences, particularly collectivism and individualism, can be found within one multicultural organization.

Cultural differences also exist among different age groups, such as between the Baby Boomers and Generation Y (Alsop, 2008). The aging population in the Western world has led to delayed retirement and a need for effective integration of older workers, including in the use of newer technologies (Hesketh et al., 2011).

Workplaces are diverse, and this diversity has both advantages and disadvantages as new waves of technology take effect. Cultural issues can arise with the use of different media. The use of videoconferencing and e-mails could exaggerate cultural and age differences where cues and jargon from those of a particular ethnic background or age group are misunderstood by others (Tannenbaum et al., 2012). Another problem that can cause difficulties is when staff from the same ethnic background communicate with each other in their native language, especially when there are tensions between managers and workers. There is a growing body of research addressing new digitally-based modes of communication and associated cultural issues (Kappas and Kramer, 2011). This is an area of research likely to increase in the next decade.

Despite the challenges, diverse workforces can result in better decision making, higher creativity, and innovation, more marketing opportunities to different ethnic communities and age groups and better and more economic opportunities. The challenge for management is to use technological developments positively to create a productive social and work climate. In the next section we use several examples to illustrate the implications of the digital revolution on the social and managerial systems with a focus on the diversity of the workforce.

Implications of Technological Change for the Culturally Diverse Social and Managerial Systems

Three themes will be used to illustrate the implications of technological change for the social and managerial system.

First, the ways in which social media is affecting employment practices in a transnational and multicultural context will be examined. Second, the impact of smart technologies and the digital revolution on individual and team work will be illustrated. Finally, there has been a significant increase in the amount of data in the world in the last few years. This potentially rich management tool and source for insights into organizations and individual workers is considered in the context of the new discipline of behavioral analytics, which is also referred to as behavioral informatics.

The Impact of Social Media on Employment Practices

Social media refers to web-based dialogues between communities, organizations, and individuals. It covers collaborative projects such as Wikipedia, blogs and microblogs such as Twitter, content communities such as YouTube, and social networking such as Facebook (Wilson et al., 2012). It assisted the Arab Spring in North Africa and in the Middle East in 2011 (Choudhary et al., 2012). Social media enabled people to exchange critical information and keep up with developments in these important events. Wilson et al. (2012) highlight the potential role of Facebook and other social media in researching cultural and other demographic differences.

In the employment context, it can be used for a variety of purposes such as finding passive information on potential employees. It can allow those seeking work to place resumes, photos, and postings thus giving recruiters easy access to a large talent pool around the world regardless of nation, culture, and race (see Brown and Daly, 2011, for comment). A complementary use of online services is to match candidates to jobs to improve retention levels and to reduce costs. Another use is microwork. This is a social media application using what is called crowdsourcing (Bohannon, 2011; Hoffman, 2012) to recruit temporary workers to do very small tasks for small amounts of money. An example of this is Amazon's Mechanical Turk that was originally created to have workers do simple tasks that computers find difficult to do (Hirth et al., 2011).

A new development with social media is that staff can market an organization's products and services through their social media connections and correspondence such as their tweets and blogs. It is reported that people are being scored for how influential they are on the Internet, and applicants for jobs are being eliminated because their scores on this construct are too low (Smith, 2012). It is now considered important for people to expand their social footprint regardless of their background and geographic location to enhance their employment and career prospects. Social media is transcending national and cultural boundaries and opening a market for talent to employers as well as giving many employees access to jobs previously denied because of geography, race, culture, and age.

Technological Change and the Nature of Individual and Team Work

The growth in communication technologies has made it possible to provide flexible work arrangements that are no longer restricted in time and space and that increasingly involve the integration of smart technologies. Although the uptake of flexible work arrangements has been slower than one might have expected, the new technologies do have implications for the way in which work is distributed and monitored.

Smart technologies in the form of smart agents in computers may replace human experts that individuals and team members can consult on a range of issues. Social robots (Fisher, 2011) that have personality are being integrated into teams and the work context. Avatars, which are computer representations of people and can act as their alter egos, are being employed. Social robots pose challenges including that they can invade workers' personal space and may be seen to be intrusive. They can tap people's need for affiliation and intimacy but the interactions are with machines without feelings and which can be socially clumsy (Midha and Nandekar, 2012). Feil-Seifer and Mataric (2011) outline a range of ethical issues needing further attention as socially assistive robotics increases.

Tannenbaum et al. (2012) point out that many teams now function in a more fluid, dynamic, and complex environment than in the past. They operate with looser boundaries and are more likely to be culturally heterogeneous, reliant on technology, geographically dispersed and in different time zones. These changes are being driven by the need for economic efficiencies including becoming leaner, quicker, and more responsive. Technological innovations coupled with costs of travel are enabling the use of virtual teams. Teams, as a result, are formed, reconfigured, and sometimes disbanded quickly. Movement is the new norm. Flash teams, such as emergency surgery teams, can form and disband quickly. A team may have an inner core or circle of permanent workers with an outer band of temporary workers often located in geographically dispersed areas. As noted above, through the use of social media, workers will compete for work in the global marketplace rather than where they live. Keeton et al. (2012) highlight space teams as the ultimate high technology, distributed, multinational, and multicultural team structure. They point to lessons learned from delayed communication between the spaceflight team and mission control that may be relevant to telecommuting. Selection of team members for technological and intercultural competencies in these situations is critical.

Managers will face challenges dealing with fluid teams and organizations (Galbraith, 2010) where individuals have membership of multiple teams all of whom have varying ties to the organization or the core of the team. The lack of clarity in boundaries creates difficulties in establishing team identity. Management may need help in selecting team members to optimize team cohesion, identity, shared purpose and performance (Tannenbaum et al., 2012), and more sophisticated methodologies will be needed to research and understand team performance (Kozlowski and Chao, 2012). Communicating to workers in different time zones is another challenge and managers will need to be cognizant of worker burnout and resentment because of the round-the-clock working day. Issues of trust will arise as managers will have to put in place measures that monitor individual and team activities to ensure that work is done and that privileges are not misused and abused (De Jong and Dirks, 2012).

How workers and work teams interact with social robots, avatars, and other smart agents will also test the capabilities of managers. Workers have interacted with robots on production lines for decades and they have recently learned to work with them on the battlefield. They will now have to learn to work with social robots in the office, at home, in hospitals, and in many other venues. Robots will soon be ubiquitous in that they will be found everywhere. Different cultural and age groups will react in various ways to these new forms of work involving social robots and avatars, providing important challenges in traditional areas of applied psychology such as selection, training, organizational change, and research (Kozlowski and Chao, 2012).

Use of Behavioral Analytics

Behavioral analytics can potentially help management make sense of the vast array of data available in digital form (Brown et al., 2011) in this digital age. Behavioral analytics emerged around 2005, as part of broader development of analytics which combines the digitally enabled upward surge in data with the use of statistical, machine learning, and operations research techniques to discover patterns and trends in data and to develop models that classify, predict or perform other functions (Davenport, 2010). Analytics as a term is generally used to refer to those quantitative and linguistic-based disciplines, such as natural language processing that extract knowledge from data to assist people to understand issues and to reach decisions (Benitez et al., 2012).

Breiman (2001) contrasts behavioral analytics and behavioral science in the context of the discipline of statistics, arguing that data-driven behavioral analytics complements the theory or model-based behavioral sciences. Those who do behavioral analytics discover, explain, and predict behavior based on knowledge extracted from data, while those who do behavioral science develop models or theories and then check if the data support them.

Behavioral analytics can be applied to a wide variety of issues including organizational change, consumer choices, regulatory behavior to understand compliance with government programs and to the analysis of performance to understand what gives athletes a competitive advantage. Behavioral analytics can be applied to the workplace to examine industrial production processes, how people and teams learn and evolve and the impact of generational change. Specific examples where behavioral analytics has been applied in the workplace include: fraud detection (Ngai et al., 2011), educational analytics (Baker and Yacef, 2009), and team dynamics (Murase et al., 2012). Murase et al. illustrate how network analytic methodologies can be used to capture the multilevel, distributed, longitudinal, and evolving nature of teams and team activity by leveraging 'the large volume of digital traces these teams generate' (p. 44). Research into complex dynamic behavior that has been comparatively neglected over decades because of limited data capture and analysis tools are now possible through digital capture of ongoing interactions with technology and new analytic approaches able to deal with voluminous data.

An example of behavioral analytics is a study of e-mail use (Fidock and Carroll, 2011). This is a social-technical study of how practitioners engage in developing, managing, and implementing systems that support cooperative work and communication. The researchers developed a model of technology appropriation to describe the processes through which users adopt, adapt, and then incorporate technology with their personal, social, or work practices. This approach sees people shaping and being shaped by systems they use. The researchers found from the study of e-mail usage that management must find a balance between being prescriptive about system use and allowing staff enough freedom to find innovative ways of using system and procedures to support their work. Participants do not simply adopt a technology and employ its features in a way consistent with the technology's intended use based on its design, functionality, and other characteristics. Instead users make choices about how to modify the technology and its characteristics to best meet their work preferences and circumstances. The researchers counseled that the design of new technologies should be an evolutionary process where design continues at the same time as a solution is being evolved and implemented and as users take ownership of it and adjust it to suit their needs.

Research Issues Requiring Further Research

There are many issues covered above that require further research. Several stand out including:

- Retraining of workers displaced by technological change and how they can quickly and effectively be reskilled to work in socially diverse and technologically changing environments.
- The social psychology of robots and workers and how they can interact effectively to achieve mutual outcomes. Social robots are reported to be awkward and socially clumsy. Research is required into how workers can develop trust in social robots and can work together to raise productivity (Kappas and Kramer, 2011).
- The most effective digitally enhanced modes of social and other communication across time, space, and culture.
- Social media and recruitment and how to prevent this process being misused and abused by employers where it discriminates against employees based on race, color and creed and based on what it reveals about applicants that is private and intrusive.
- Preparation of staff to manage at a distance or what is referred to as 'remote management'. There will be many challenges for managers coordinating and controlling workers with different qualifications and skills and from different cultural backgrounds and working in different locations in the world. An added difficulty will be how they manage smart technology as well as smart people.
- Exploration of new applications of behavioral analytics to a wide range of fields in applied psychology, especially as a sophisticated tool for research (see, for example, comment by Collins, 2012).

Technological Determinism

Ronald R Kline, Cornell University, Ithaca, NY, USA

Abstract

'Technological determinism' is a term used to describe a set of claims made about the relationship between what we generally call 'technology' and 'society.' Two meanings have come into use: (1) an internal, technical logic determines the design of technological artifacts and systems; and (2) the development of technological artifacts and systems determines broad social changes. The second claim is much more common and is often associated with debates over Karl Marx's theory of history. But the two meanings are often conjoined in the claim that an autonomous technology (in both its development and use) shapes social relations. Other claims are less strong and express the belief that technology is a major cause, but not the sole determinant, of social change. Although scholars have argued for many years against the strong version of technological determinism, the general belief that technology is a major force shaping society, which dates to the early nineteenth century, still pervades popular culture in the United States and Europe. Ironically, critics of the harmful effects of technology tend to reinforce the strong claims of technological determinism. Methods developed to analyze the social construction of technology have moved the debate from questions like 'does technology drive history?' to arguments about a mutual relationship between technological and social change. New research recommends taking technological determinism seriously in order to understand its justificatory role in developing and using sociotechnical systems.

'Technological determinism' refers to a pervasive, yet controversial, theory about the relationship between technology and society. Although the term has had a variety of meanings, two related claims have been central to discussions of this topic: (1) the development of technology proceeds in an autonomous manner, determined by an internal logic independent of social influence; and (2) technological change determines social change in a prescribed manner (Staudenmaier, 1985; Misa, 1988; Bimber, 1994). The claims address two major questions about technology: how and why is technology developed and what is the relationship between technological change and social change? Arguments against the first claim have been a staple of research in the history and sociology of technology since the 1960s. The second claim has been at the center of debates about Karl Marx's theory of history since the early twentieth century. Weaker versions of technological determinism, sometimes called 'soft determinism,' maintain that technology is a major cause, but not the sole determinant, of social change.

History of the Concept

It is important to distinguish between widely held beliefs that an autonomous technology is the primary cause of social change and the use of the term technological determinism. In the United States, the Enlightenment doctrine that improvements in the mechanic and industrial arts fostered social progress was replaced over the course of the nineteenth and early twentieth centuries by a more technocratic concept of progress, in which improvements in technical and economic efficiency become ends in themselves, instead of the means for creating desired social ends. Through the writings of the economist and social theorist Thorstein Veblen and others, the word technology gradually displaced phrases like 'mechanic arts' in scholarly and then popular discourse in the twentieth century. In this period, the older meaning of 'technology' as systematic knowledge of crafts and industry was joined to the anthropological one of the artifacts and related practices of a culture (Schatzberg, 2006). The term's connotations of abstractness, scientific objectivity, and masculinization served to reinforce the idea that technology was an autonomous social force (Marx, 1994, 1997; Oldenziel, 1999).

These meanings entered popular culture through such media as utopian novels, exhibits at World's fairs, the Technocracy movement in the 1930s, and company advertisements that endlessly touted new products as the cure for social ills and the source of all happiness. The organizers of the 1933 Chicago World's Fair encapsulated the gender biased, applied science aspect of technological determinism with the motto, 'Science Finds, Industry Applies, Man Conforms.' Ironically, twentieth-century critics of technology's harmful effects, such as technological unemployment and environmental degradation, have tended to reify the notion that technology is an autonomous agent of change in their attempts to control it (Smith, 1994).

The term 'technological determinism' is more recent, with roots in the turn-of-the-century debates about Marx's theory of history. While Europeans used the phrases 'historical materialism' and 'economic determinism' to describe Marx's theory, many American social scientists employed the broader phrase, the 'economic interpretation of history,' popularized in a non-Marxist manner at the turn of the century by Edwin R.A. Seligman, editor-in-chief of the first edition of the *Encyclopedia of the Social Sciences*. Historian Werner Sombart in Germany and economist Alvin Hansen in the United States argued that Marx's theory should more properly be called a 'technological interpretation of history.' Although many scholars questioned this view, prominent Soviet theorists established a 'technicist' version of historical materialism as the dominant interpretation in orthodox Marxism during the first half of the century (Bober, 1927; MacKenzie, 1984; Miller, 1984).

During the early Cold War, social scientists and historians, who were increasingly concerned about how to control the

effects technology apparently was having on daily life, increasingly used the starker term, 'technological determinism' to criticize Marxist theories of technology and society. They also used the term to criticize the controversial views of such authors as Veblen, historian Lynn White, Jr., and the philosopher Jacques Ellul. White and Ellul said their views did not amount to a strict determinism. Only a few authors, such as economist Robert Heilbroner (1967), have labeled their own position a form of 'technological determinism' (soft determinism in Heilbroner's case). Philosopher Langdon Winner criticized scholars for dismissing the issue of technology's social effects because of the flaws in the concept of technological determinism. Saying that the "idea of determinism is not one that ought to be rejected out of hand," Winner argued that technology does constrain human activities (Winner, 1977: 77).

By the mid-1970s, the issue of technological determinism had become a central topic in both Marxist scholarship and in the interdisciplinary study of science, technology, and society (Cohen, 1978; Staudenmaier, 1985). In line with the more recent turn toward social constructivism in the latter field, the issue of technological determinism became (and remains) a focal point around which to criticize a theory of technology and society that is still prevalent in other disciplines and in popular culture.

Was Marx a Technological Determinist?

Scholars are sharply divided about whether or not Karl Marx's theory of history, the *locus classicus* of technological determinism, is indeed technological determinist. Much of the debate centers on the meaning of an often-quoted excerpt from the preface to Marx's *A Contribution to the Critique of Political Economy* (1859): humans enter into "relations of production [*Produktionsverhältnisse*] which correspond to a definite stage of development of their material productive forces [*Produktivkräfte*]. The sum total of these relations of production constitutes the economic structure [of society], the real basis on which arises a legal and political superstructure" (quoted in Cohen, 1978: 28).

Those who argue for a technological determinist interpretation of Marx usually equate "material productive forces" (or "forces of production") with technology and interpret the verb 'correspond' to mean that the relations of production evolve to maximize the productivity of the forces of production. William Shaw, who includes instruments, raw materials, and labor power (including knowledge) in the category of productive forces, defines Marx's "technological determinism" more properly as a "productive-force determinism." Shaw acknowledges that Marx allowed for interplay between forces and relations of production, but maintains that productive forces are the "long-run determinant of historical change" (Shaw, 1979: 160). Gerald Cohen defines productive forces in a similar, broad manner, but rejects the label of technological determinism in favor of a "'technological' interpretation of historical materialism." In this functionalist view, social structures adapt to technological change to increase productivity (Cohen, 1978: 29).

Those who argue that Marx was not a technological determinist typically have concentrated on the manner in which he wrote history. Harry Braverman, Nathan Rosenberg, and Donald MacKenzie point to the dialectical aspects of Marx's writings, especially where he attributed the development of productive forces to social relations. Indeed, MacKenzie characterizes Marx's treatment of the history of machinery in the British Industrial Revolution as an "attempt to develop a theory of the social causes of organizational and technical changes in the labor process" (MacKenzie, 1984: 492). Richard Miller argues that Marx was not a technological determinist because, in his historical work, "economic structures do not endure because they provide maximum productivity. Productive forces do not develop autonomously. Change in productive forces, in the narrowly technological sense that excludes work relations, is not the basic source of change in society at large" (Miller, 1984: 188). Bruce Bimber, who defines technology narrowly as artifacts, argues that, for Marx, human characteristics of accumulation and self-expression drive the forces of production. Accordingly, Marx was an economic, not a technological, determinist (Bimber, 1994). From a linguistic perspective, Raymond Williams argues that Marx's usage of the German verb *bestimmen*, usually translated as 'to determine,' in key passages denoting the relationship between the mode of production (base) and the realm of culture and ideology (superstructure), refers to a "notion of determination as setting limits, exerting pressures," rather than a prefigured determination (Williams, 1973: 4).

Varieties of Technological Determinism

Bimber and Thomas Misa effectively analyze varieties of technological determinism. Bimber (1994) distinguishes between normative, nomological, and unintended-consequences accounts. Normative accounts, evident in the writings of such critics of technology as Lewis Mumford, Jacques Ellul, and Jürgen Habermas, claim that society is relinquishing control over technology, or replacing political and ethical norms with those of the technologist's goals of efficiency and productivity. Nomological accounts, such as that by Heilbroner (1967), evoke the two-part definition of technological determinism given above: technology develops autonomously according to an internal logic and forces a prescribed social change. In unintended consequences accounts (e.g., Winner, 1977), technology produces unpredictable social change, a view that challenges determinism, but reinforces the idea that technology is out of control. Bimber argues that the term 'technological determinism' should be reserved for nomological accounts, which are the only ones that satisfy his strict definition of the term.

In his survey of scholarship about the relationship between technology and social change, Misa (1988) found that sweeping, macrolevel accounts were more likely to be technologically deterministic (using the two-part definition of the term) than microlevel accounts, which focused on specific practices. Philosophers, business historians, urban historians, and historians of physical sciences were generally more deterministic than technological historians and labor historians.

Another form of technological determinism is what Claude Fischer (1992) criticizes as the 'impact-imprint' model of technology. Rather than investigating how consumers use

a particular technology, scholars assume that a technology's capability (e.g., the ability of the telephone to enable people to talk at a distance) leads to a predictable 'impact' (e.g., new, long-distance communication patterns).

Political Artifacts and Systems

Winner and Thomas Hughes have proposed influential theories of technology and society that address the question of technological determinism. Winner (1986) argues that artifacts have politics (i.e., are associated with specific social changes) in two ways. First, technologists can design a (plastic) artifact to promote a certain type of politics, as when Robert Moses built low bridges over the Long Island Expressway in order to prevent inner-city buses (carrying poor minorities) from traveling to Jones Beach. Second, the design and building of some systems seems to require a certain type of politics. Nuclear power plants, for example, require a centralized form of government to run the reactor and prevent the proliferation of nuclear weapons. (For a criticism that the low-bridge example does not take the tradition of expressway building into account, see Joerges, 1999). Hughes (1994) states that his concept of technological systems allows for the social construction of a system when it is young, but technological determinism comes into play once it is established and has 'technological momentum.' From that point on it shapes society more than being shaped by society.

Social Construction of Technology

The advent in the mid-1980s of the approach known as the social construction of technology (SCOT) (Pinch and Bijker, 1987), along with a contextualist history of technology (Staudenmaier, 1985), has challenged the technical aspect of technological determinism (the first part of the definition given above). Sociologists and historians of technology have published numerous case studies of the development of technologies that argue that their design was the outcome of negotiations between several social groups (such as inventors, engineers, managers, salespersons, and users), rather than the product of an internal, technical logic (*see* Technology, Social Construction of). When Winner (1993) and others criticized this approach for leaving out power relations among social groups, constructivists responded by investigating the social aspect of technological determinism (the second part of the definition). Bijker (1995) employed a semiotic version of Michel Foucault's "micropolitics of power" to show the mutual construction of artifacts and social groups. Ronald Kline and Trevor Pinch (1996) utilized theories of gender in the original SCOT approach to show how gender relations and the automobile were mutually constructed when farm men in the United States before World War II adapted the car, as a stationary and mobile source of power, to a variety of novel uses, such as grinding grain, washing clothes, and plowing fields. Fischer (1992) employed a similar user-heuristic to argue that callers in the United States used the telephone before 1940 to widen and deepen existing communication patterns, rather than to create new ones. Kline (2000) extended that analysis to show how farm men and women wove several so-called 'urban' technologies (the telephone, automobile, radio, and electric light and power) into their lives, creating individual versions of 'rural modernity.'

Reconsidering Technological Determinism

The work by Bijker, Kline, and others on the mutual construction of technology and society resonates with recent calls to reconsider the dismissal of technological determinism in the history and sociology of technology. Rosalind Williams has asked historians of technology to drop their objection to the concept and become willing to "taste the forbidden fruit of technological determinism" by paying much more attention to the social and cultural changes involved in using technology (Williams, 2007: 104). Sally Wyatt has argued that science and technology studies (STS) scholars "must take technological determinism more seriously, disentangle the different types, and clarify the purposes for which it is used by social actors in specific circumstances." By recognizing four types of distinct rhetorical treatments of determinism (justificatory, descriptive, methodological, and normative) and reflecting on their personal attitudes toward technological determinism, Wyatt argues that STS scholars can deepen their "understanding of the dynamics of sociotechnical systems and the rhetorical devices of some decision makers" (Wyatt, 2008: 169, 176). Other sociologists of technology have taken up the concept of the social 'affordances' offered by technology, even when those are socially constructed (David and Pinch, 2006). These efforts are part of a larger movement to go beyond the original aims of SCOT in order to understand how using technology shapes society in a nondeterminist manner (Kline, 2013), in this case by studying what work the (academically discredited) belief in technological determinism does in promoting new technologies.

Technology and Organization

Abstract

The term 'technology' is in common everyday use. It may be popularly visualized in purely physical terms as 'equipment,' 'apparatus,' 'pieces of hardware and software,' and it may be defined by different commentators in different ways. Whatever the case may be, what is much more serious than definitional problems are the practical implications of the development, implementation, and control of technology by *a few* for the use of *the many* in an organization and in wider society. This article addresses the issue of technology and the relationship between technology and 'organization.'

Organizing and Organization: An Overview

To initiate a discussion on the relationship between organization and technology, it is important first to define what is meant by each of the two terms. First, what is meant by the term 'organization'? Well, to organize something is to 'systemize' it for a certain desired end. 'Organizing' a group of people is a process that aims to give an orderly structure to that group with a view to achieving a goal or fulfilling an objective in mind. In such a process the group in question acquires, or is brought into, a state of being 'organized.' This definition is quite a broad one; it is meant to be so, since an encompassing conceptualization of the term is required to grasp the range of possible positions and influences of technology in and on organizations.

From an organizational studies perspective, organizations are defined as social arrangements for the controlled performance of collective goals (see Huczynski and Buchanan, 1991; Scott and Davis, 2007). In a broad sense, therefore, examples of an organization may include an African tribe, Juventus Football Club, a consumer electronic goods manufacturer, the European Union, or the University of Harvard.

Defining Technology

Technology has received increased attention since the late twentieth century because of the pace of technological advancement and the magnitude of its diffusion in society. Indeed, it is likely to impose itself as a pivotal organizational issue more forcefully than ever before because of the pervasiveness of 'new' technology and its effects on organizing and on the structure and functioning of organizations as well as the behavior of individuals and groups within them. Examples of new technologies include information technology, biotechnology, materials technology, space technology, and nuclear technology.

But what is technology? Well, again there is no single answer to this question, although to a layperson it is merely 'equipment,' 'apparatus,' or 'pieces of hardware and software.' Even among commentators in the field of organizational studies, differences can be found as to how technology is defined. Regardless of the way it is defined, however, technology is an important factor in organizing and organizational life. A suitable working definition for the purpose of this article is that, in essence, technology is a man-made creation of a *system* that is supposed to work logically and consistently, and is made operational to produce a desired accomplishment that is valued by its inventor or user. Such an accomplishment is often reproducible, through the system, to a given set of performance criteria or precision.

The creation of such a system involves translating some pure science knowledge into an *input–conversion–output* system format based on engineering principles and composed of elements that are functionally arranged or configured so as to yield a certain output as specified by the designer or user (see Clark et al., 1988). According to this definition, technology is defined not only in terms of its physical objects but also in terms of its methods of operation, use, or production and the technical know-how needed to apply them successfully. Human intervention in the operation of a system usually takes the form of monitoring the system's conversion process and controlling its output through a specific feedback mechanism.

Conceptualization and Meaning: From Neutral Rationality to Political Sensitivity

Conceptualization of technology merely in terms of 'equipment,' 'apparatus,' or 'pieces of hardware and software' carries with it shades of pure rationality in mind. This conceptualization depicts technology as nothing more than a physical construction of a proven scientific idea or inference. The emphasis here is on technology as a manifestation of a purely logical effort, which produces a neutral 'object' or 'pattern of operation' that helps mankind per se rationalize a given work task or improve the quality of a certain aspect of social or work life. This is often achieved by substituting human effort with machine effort, a phenomenon which began historically with physical effort (mechanization) and continues today with human coordination and intellectual efforts being replaced with inputs from 'smart machines' (computerization and automation). This takes place in an information age where information technology has become part of a global culture and knowledge-based artificial intelligence is likely to progress further. Thus far the notion of technology could be described as an objective description of an outer form of a disinterested, 'inanimate' object or mechanistic pattern of operation.

The above chosen *system* definition of technology, however, goes beyond this rather simplistic conceptualization as it takes

on board the role of the designer or user in *configuring* a system that gives an output in accordance with the designer's pre-specified performance criteria. Therefore, the proposition that technology could be explained merely in terms of presumed neutral rationality grounded in a specific scientific logic appears suddenly to be in question as a credible explanation because of the interference of the subjectivities of those associated with its instrumentalization and operation in the real world.

Just how politically sensitive technology is can be illustrated by explaining how significant it is to organizing and organizations. This is a turning point in conceptualizing technology as a serious organizational development involving actual and perceived impacts of a system's output upon organizing and within organizations. In this sense, technology is capable of being socially divisive (Leonardi and Barley, 2008). That is, a system's output can and does affect the status quo of any organization that accommodates it or comes to live under its influence. This will have implications for any long-established equilibrium in relationships, balances of power, and any sense of continuity within the organization. It may also have implications for the wider industrial sector or economy in which the organization operates and with which it interacts. Additionally, it may indeed have implications for the environment (e.g., pollution and health hazards in the case of a nuclear technology). Since differences of interpretation among individuals and groups will inevitably occur in the world of meaning, a system's output will signify and symbolize different things to different people; it will be highly valued by some but not by others; it may seem useful to some as something that improves the quality of working life, for example, and harmful to others who see in it a threat or deterioration. In short, it is liable to being controversial and bringing about a sense of dispute as to why it has been acquired in the first place and, now that it has, how it should be managed and controlled to minimize its potential damage.

Furthermore, what makes technology a politically sensitive issue in organizational life is the fact that invariably technology is decided upon, adopted, designed, implemented, and changed by a minority of people in an organization (e.g., managers) on behalf of the majority of the organization's members (e.g., employees) who have to live with the consequences of operating it as an integral part of their jobs. Nonusers are also likely to be affected, in that their jobs will now require different coordination skills to keep them in harmony with a changed rhythm and workflow throughout the workplace, for example, where new production methods are introduced by management. A common concern for users and nonusers alike may be that the introduction of a new *input–conversion–output* system format into the workplace is going to disrupt stability and that they have to change their working methods in order to suit the operational requirements of a new and somehow threatening technology-dictated work system.

By the same token, technology, at a societal level, is often invented by a single individual (e.g., a scientist) or an elitist minority in society (e.g., a technology research center or a team of top biochemists); it is commercialized, marketed, and diffused by another minority (e.g., entrepreneurs or manufacturing companies), who are driven by a different set of motives (e.g., profit-making); it is regulated and controlled centrally by yet another minority (e.g., a sovereign state's legislature or a federal government). Yet, this technology is highly likely to be consumed by the vast majority in society. Even nonconsumers are likely to be affected by it in either a positive or negative way, or both. Because of this minority–majority situation, technology acquires necessarily social, economic, and political implications as well as rational, logical, and technical significances.

It is no wonder, therefore, that the politics of organizational change are increasingly accomplished through technologies in a digital age. Many of the most radical redesign projects for organizations have been in and through the use of digital technologies: from computer-integrated manufacturing to process reengineering in manufacturing industry; from projects for 'virtuality' to extensive teleworking, organizations are being sold on projects of technical rationality as visions for the future. Yet, so many of these projects appear to be stillborn: the technologies work, but the organizational designs do not. Sometimes people sabotage the technologies; other times the technologies sabotage them. In a way, organizations are reduced to criteria of design from which most considerations of the politics of organizational change are absent. This is often the case even where the projects are explicitly political or require explicit politics to manage their changes. It is the politics of organizational change technologies that make the critical difference: How, and whether, they work?

The Relevance of Technology to Managing and Management

It would be misleading to suggest that management should constitute a homogeneous team making rational decisions. Different levels and functions of management within an organization tend not to be a single social or political decision-making group sharing a single rationality; these will therefore tend to hold different perceptions of technological change and are likely to differ among themselves as to how it should be managed (see Pettigrew, 1985). Yet, it is clear from the discussion so far that an organization includes people who, because of their membership of a collective social group, interact with one another in certain ways to achieve goals which if they act alone they cannot accomplish. Since it is management's responsibility to have work tasks carried out by employees, in the context of a business organization, for example, it follows that the impact of technology is of central concern to managers per se, particularly those who are in charge of implementing projects involving the introduction of a new technology. Planning, control, implementation, and evaluation activities relating to such projects require decisions to be made, ranging from individual motivation through job design to the management of change and coordination of a newly designed work organization. Such decisions are made by managers occupying different positions within an organization's management structure. Regardless of how successful or unsuccessful those decisions will come to be judged by others, it is *management* as an institution that is going to be judged in terms of its rationality and political sensitivity as well in terms of its dominant attitudes, values, and ideological persuasions.

Whatever the type of organization or management an external observer chooses to study, technology is relevant to

organization because the latter is necessarily a source of the following:

1. money and physical resources, including technology itself;
2. meaning and purpose, including how different individuals and groups within an organization perceive technology in relation to these variables;
3. order and stability, including how stabilizing or destabilizing it is in the context of a change project involving the introduction of a new technology;
4. security and protection, including the consequences of change for security of employment, and health and safety concerns;
5. prestige and self-confidence, including possible improvement or degradation of job design and satisfaction following the utilization of a certain technology; and
6. power and control, including technology-related assignment of authority and shifts in the *de facto* balance of power due to empowerment caused by, for example, expert knowledge of a key technology.

Therefore, management's role in, and responsibilities for, technological change should be emphasized as a legitimate concern for an organization's stakeholders who are not members of the *governing* institution of management, because of, among other things, the strategic, operational, and control choices available to managers in planning, design, and implementation (see Buchanan, 1983; Sorge et al., 1983; Child, 1987).

The Technology–Organization Link: Empirical Studies and Theorization

The relationship between technology and organization could be perceived, explained, and theorized upon differently by different people and groups, depending on many factors as explained above. This is in harmony with a central assumption of this article, which recognizes the legitimacy of a multiplicity of views as to what constitutes this relationship.

Such multiplicity is reflected in the management literature, including major empirical studies theorizing upon the organization–technology relationship. Examples of these studies include Joan Woodward's (1965) investigation of 100 firms in South East England, which used different unit and small batch, large batch and mass, and process production technologies. The main conclusion of this study was that *technical complexity* caused increases in the length of chain of command, in executives' span of control, in the proportion of indirect to direct labor, and in the proportion of managers to the total employed workforce. The technology used to manufacture a product placed certain requirements on those who operated it, which, in turn, were reflected in the organizational structure. Woodward's variable was further studied by Charles Perrow (1976), whose name is also associated with 'technological determinism,' since he argued that specific aspects of job discretion, coordination, and group interdependence were determined by the type of technology used, much more so than by other variables such as leadership style or small group dynamics.

The Aston research program in Birmingham, England (e.g., Pugh and Hickson, 1976; Pugh and Hinings, 1976), contributed to organization theory by blending some of the research methods and assumptions of psychology with conceptions of organizations and their workings from sociology and economics. The empirical work undertaken by the Aston group aimed to link organizational structure and functioning, group composition, and interaction, as well as individual personality and behavior. It did so by researching organizational structures in terms of their degrees of 'specialization,' 'standardization,' 'formalization,' 'centralization,' and 'configuration.' According to the Aston studies, an organization's size and its dependence upon other organizations were found to be much more significant variables than technology and ownership.

Other relevant empirical contributions to theory include that of Eric Trist and his colleagues, of London's Tavistock Institute, who studied the effects of mechanization in coal mining (e.g., Trist and Bamforth, 1951; Emery and Trist, 1960). Their 'sociotechnical perspective' contributed considerably to the Quality of Working Life movement, particularly in the USA and Canada, where Fredrick Taylor's (1947) 'scientific management' style dominated the industrial scene as many large organizations followed Henry Ford's mass production model, which caused degradation in working conditions in the context of a capitalist economy.

Classical theorizing about organizational technology has produced a set of typologies for categorizing technology, which are often used to develop and empirically test contingency theories, including Woodward's (1965) above mentioned work, giving rise to the notion of 'technological imperative.' Other important issues concerning social structure are associated with the position of technology in modernist organization theory, including task interdependence, uncertainty, complexity, and change in the environment of an organization. Linear models of technological innovation are increasingly being challenged, however, by postmodernist theorists and social constructionists (e.g., Clegg, 1990; Gergen, 1992; Pettigrew, 1985), who emphasize the need for researching the contexts in which technologies are introduced.

Conclusion

In summary, this article has addressed questions pertaining to the management of technology adoption and organizational adaptation in organizations. It defined the terms organization and technology, and discussed the relationship between them. One single point remains at issue: The desire for an 'optimum fit' between the two is a noble concern, but in practical situations involving many users and a few decision makers and, equally, in theoretical situations involving numerous typologies and competing interpretations, on whose terms?

Technology and Social Control

Gary T Marx, Massachusetts Institute of Technology (MIT), Cambridge, MA, USA

Abstract

One aspect of modernization is the use of science-based technology in rule enforcement. In the 'engineered society,' an ethos of rationalization is seen in the application of means to ends. The events of 11 September 2001, and the war on terror have brought increased attention to the question, but the increased use of technical means for control reflects continuity rather than disjuncture. Six social control strategies are discussed and illustrated: target removal, target devaluation, target insulation, offender incapacitation, offender exclusion, and identification of offenses and offenders. In complex settings in a democratic society, relying primarily on technology to control human behavior has clear social and ethical limitations.

The technology's narrowing of focus may come at a cost of failing to see larger systemic contexts, alternatives, and longer range consequences. The complexity and fluidity of human situations makes this a rich area for the study of trade-off, irony, and paradox. There are some parallels to iatrogenic medical practices in which one problem is cured, but at a cost of creating another. Technical efforts to ensure conformity may be hindered by conflicting goals, unintended consequences, displacement, lessened equity, complacency, neutralization, invalidity, escalation, system overload, a negative image of personal dignity and the danger of the means determining, or becoming ends.

Introduction

Since the last half of the twentieth century, there has been a significant expansion in the use of science and technology for purposes of social control. Control through technology is central to the working of modern society. The events of 11 September 2001, and the war on terror have brought increased attention to the issue, but reflect continuity rather than disjuncture. Consider the intensification of control seen in the United States such as the Patriot Act and other legislation, and the creation of the Department of Homeland Security; vastly augmented expenditures for research and development; the international spread of tools such as DNA analysis, RFID chips, drones, facial recognition systems, enhanced travel and border controls, data-based risk management and predictive tools; and the increased sharing of information and integration among public and private and local, national, and international agencies.

Many technologies developed for the military such as the Internet, satellites, and sensors have diffused to other institutions. Yet the use of tools to engineer behavior goes far beyond particular historical events and national security to everyday life – whether this involves work, consumption, health, recreation, school, or families and friends.

The engineering of social control is one of the defining characteristics of modern society. It is so prominent, ubiquitous, and transparent in daily life that it is often taken for granted. Our personal spatial, communication, social, cultural, and psychological environments and borders are increasingly subject to technological strategies designed to influence behavior, whether involving conformity with rules, safety, consumption, or attitudes.

In some ways, contemporary social control can be seen to reflect the ethos of the highly regulated prison in which conformity is sought by designing ever more features of the environment, rather than relying on trusting the individual or facing the uncertainty of human will and choice. Are new threats, technologies, expectations, and ways of living resulting in a move toward our becoming a 'maximum security society'? The engineering of control (in both its hard and soft forms) is an important component of our contemporary *surveillance society*. Marx (1985, 1988, forthcoming) expands on these developments. On surveillance more broadly, see Lyon (2007), Ball et al. (2012) and Staples (2000), and on technologies of crime control see Manning (1992) and Leman-Langlois (2013).

A major strand of social control involves the enforcement of rules and standards. This article provides a classification framework for technology-based efforts to prevent or reduce the harm from, or attractiveness of, rule violations and, when that is not possible, to increase the likelihood of discovering and apprehending violators. Such enforcement activities are distinct from other aspects of social control such as the creation of norms, processes of adjudication and sanctioning, or the broad societal guidance and integration that was of concern to early theorists of industrialization and urbanization (Gibbs, 1989; Janowitz, 1975).

The engineering of rule enforcement involves material artifacts (architectural and product design, sensors and alarms, access controls, and software), and also is distinct from forms of social control such as the creation and manipulation of culture, socialization, the redistributive rewards and penalties of the welfare state, and other interpersonal influences that are designed to influence behavior.

Contemporary efforts build upon, but go far beyond, a medieval fortification ethos. Of course, the inventors and builders of the first locks, safes, moats, and walled castles and the developers of early biometric identification systems (e.g., the Italian criminologist Cesare Lombroso, 1835–1909) were engaged in the engineering of social control. What is new is the scale and relatively greater scientific precision, power, omnipresence, continual invention and experimentation, and rapid global diffusion. Technical means of control saturate modern society, colonizing, documenting, and in some ways restricting ever more areas of life.

The roots of contemporary social control lie in the development of large organizations and standardized control technologies (Beniger, 1986). They are one strand of broad processes of rationalization, professionalization, and specialization occurring with modernization (Weber, 1958; Rule, 1973; Foucault, 1977; Cohen, 1985; Laudon, 1986; Gandy, 1993; Zuboff, 1988; Lyon, 1994; Shenhav, 1999). The heterogeneity, scale, mobility, and anonymity of mass society and the pursuit of efficiency and effectiveness encourage reliance on external, impersonal, distance-mediated, and technical means and database memories that locate, identify, register, record, classify, and direct individuals.

The perception of catastrophic risks in an interdependent, global world relying on complex technologies drives the search for definitive technical solutions. Consider issues such as terrorism, crime, obesity, drug abuse, acquired immunodeficiency syndrome, border controls, and the need for economic competitiveness and unprecedented flows of persons, information, and goods across borders. Developments in electronics, computerization, artificial intelligence, cognitive science, biochemistry, architecture, materials science, and many other areas promise new control possibilities. Entrepreneurial efforts (whether by private sector actors such as the security industry or governments such as the United States) have helped spread the technologies at home and abroad.

This use of contemporary technology contrasts with traditional approaches in which environments were less likely to be designed with rule enforcement in mind. Nor was there much probing beneath personal informational borders *before* untoward incidents occurred. Current preventive and anticipatory responses contrast with earlier reactive forms of control in which enforcement agents tended to become involved only *after* violations occurred and in a specific rather than a categorical fashion.

The engineering emphasis may be on environmental conditions, control agents, or actual or potential offenders and victims (sometimes the categories overlap). Consistent with the classical deterrence ideas that Thomas Hobbes (1588–1679) emphasized, some strategic efforts aim to create self-control and rational calculation on the subject's part others, however, seek greater certainty through applying hard engineering means believed to make the violation impossible. Rather than attend to the consciousness or will of subjects, the emphasis through automation is on eliminating, or at least significantly inhibiting, their ability to violate rules. Engineered efforts also seek to limit the ability of social control agents to demonstrate incompetence, mistakes, corruption, or discrimination, as the machine is geared to get 'the human out of the loop.'

Software programs aimed at prevention and early intervention have proliferated. There are many actuarial assessment protocols that profile and assign predictive scores to places and persons with respect to their presumed threat, vulnerability, and risk (Ericson and Haggerty, 1997). This has resulted in the expansion of various kinds of watch lists for at-risk populations such as the mentally ill, sex offenders, and those believed to be at risk of becoming homicide offenders or victims.

Any effort to *influence* persons or events can be seen as a form of engineered social control using tools exerted by an *agent* on a *subject* (or a population of potential subjects) or on an object. Engineering is present whenever a strategy based on beliefs about means–ends relations is applied and need not involve material factors. Prayers as well as magical practices would thus be examples, although they are far from the direct science-based efforts of interest here that involve rule enforcement. Failing to take any action as part of a strategy to avoid seeing a situation escalate is also an example.

Closer to the topic of the present article, although also distinct, is the design of presumably failsafe products *automated* for safety, such as the 'dead man's switch' on a train or the protective shield on a table saw – mechanisms that are intended to transcend human will. Engineering is also present in the *nonautomated* situations designed to persuade or guide behavior (but with choice remaining), such as advertisements for a negative political campaign or to discourage smoking, a waiter reciting the kinds of beers offered by moving from the least to the most expensive (anticipating that the customer will be prone to opt for the most recently mentioned beer), manufacturers increasing the nicotine or sugar content of cigarettes and food, or providing uncomfortable seating in fast-food restaurants to encourage rapid turnover. Also related are strategic efforts that permit, or even facilitate, *rule violations* through deception or reverse engineering. Consider police undercover operations, or online frauds that spoof computer security or create situations that permit blackmail. While sharing strategic logic, the above efforts are distinct from rule enforcement efforts.

Six Strategies

This section considers six engineering (primarily machine- or material-based) efforts to eliminate or limit violations by control of the physical and social environment, rather than by mere appeals to doing the right thing (or at least what an agent desires). This is followed by discussion of some social and ethical implications of such efforts.

The six ways of controlling persons and/or environments emphasize protection/alteration of the victim or the object of the violation (such as a car). Such actions make it impossible or at least more difficult or less inviting for the potential offender to act; or should prevention fail, tactics are intended to increase the likelihood of identification and apprehension. Some engineering efforts involve traditional notions of target hardening, but the engineering of control may also involve the idea of suspect softening or weakening.

Strategy 1 (and sometimes 4 and 5 below) includes *primary* direct prevention efforts. These are designed to eliminate the offense, or increase the difficulty of carrying it out. With the primary engineering strategy it is not necessary to affect the will or calculation of the potential rule breaker. The subjective orientations of the actor (whether based on calculation, a content-filled socialization, or a contentless discipline) are simply ignored. The emphasis is on altering opportunity structures and capabilities rather than the person's conscious choices. The social engineering example of castration as a device to control sexuality (whether literally or, as currently

may be done, chemically) clearly contrasts with appeals to virtue to accomplish the same end.

But primary strategies are not always available and may not live up to their promise. Hence, one sees a series of *secondary* engineering strategies (2, 3, 5, and 6 below) where concern with the will of the violator can be a factor. The more traditional goal of deterrence may be pursued by affecting the calculations of potential violators through devaluing and insulating targets, increasing the costs of nonconformity, and increasing the likelihood that violations and violators will be discovered and that evidence can be traced. What cannot, literally, be prevented may nonetheless be deterred by eliminating the gain, altering the cost-benefit ratio, or enhancing the chances for identification and apprehension.

As in other areas of social intervention such as public health, contemporary approaches place strong emphasis on preventing and minimizing harm. Rather than relying on persuasion (which assumes situations in which individuals have a choice about whether to respect a rule or to behave in a way that an agent wants them to), the emphasis is on direct technological interventions to design problems away. Ideally, problems are anticipated and eliminated (1, below); or where that is not possible, the goal is to create deterrence by reducing the gain (2), making violation more difficult and more costly (3, 4, 5), or by increasing the likelihood of identification and apprehension (6).

Target or Facility Removal

The logic of prevention is clearest and most effective here. Something that is not there cannot be taken or used. The move toward a cashless society is one example. Merchants who only accept credit or debit cards, or whose registers never have more than a modest amount of cash in them, are unlikely to be robbed by conventional means. Furniture built into the wall cannot be stolen. Subway cars and buses made with graffiti-resistant metals are hard to draw upon. Police stings that pass off a harmless white substance as cocaine or that substitute fake for real dynamite or provide inoperable weapons offer evidence of intent to commit a crime, but preclude harm resulting from it. Conversely, deception as disguise may work in the other direction: hiding the appearance of something valuable, as with painting gold ingots black.

Target Devaluation

Here, the goal is to reduce or eliminate the value of a potential target to anyone but authorized users. The target remains, but its uselessness makes it unattractive to predators. Examples include products that self-destruct, as with some car radios when stolen, or that leave clear proof of theft, as with exploding red dye packs that stain money taken in bank robberies. The broken tamper proof seal on food products is intended to deter those who would tamper, and serves as a warning. Another type of example is telephones, computers, automobiles, and even guns that require a unique, presumably nontransferable biometric means of identification (e.g., retinal, voice, or geometric hand pattern) before they can be used. Disposable access codes that can only be used once need not be protected. Encrypted messages can often be easily intercepted, but without the decryption code the data are useless. As an antiteenager congregating tool, some mall shops play classical music in front of their stores.

Target Insulation

With this ancient technique, the object of desire persists but is protected. Perimeter maintaining strategies such as fences, walls, moats, guards, and guard dogs can be distinguished from more specific protections surrounding an object such as safes, armor, chastity belts, and goods that are in locked cases or chained to immovable objects. Other examples involve the hiding or disguising of valuables or persons. Still other examples involve high security, such as in gated communities where access and egress is carefully controlled, or make use of networked sensors, alarms, internet video, and bulletproof barriers, such as in banks separating customers from tellers (a form in Europe controls both entry into and exit from a bank through an enclosed booth). The architectural development of 'skywalks' linking downtown private buildings creates 'sanitary zones' more subject to control than the potentially disorderly public streets below. Softer forms of border protection lie in the use of access codes based on pin numbers, passwords, and biometric measures. Schools and after school programs can be seen as 'safe houses' in which the young are protected from offenders (and not incidentally school officials can watch the contained children for appropriate behavior).

Offender Weakening or Incapacitation

This classic strategy seeks to render potential offenders harmless by disabling or weakening their will or ability to violate the norm in question, or, if the violation occurs, to escape. The means may act directly on the body by permanently altering it and making certain offenses impossible – cutting off the hands of thieves – or at least uninviting, as exemplified in the operant conditioning seen in the novel *A Clockwork Orange* (Burgess, 1962).

A negative association with a particular form of undesirable behavior may be created. After ingestion of a substance such as antabuse, an unpleasant physical reaction (gagging or vomiting) follows when alcohol is consumed. The morphine derivative trexan is used to detoxify methadone as a remedy for heroin addiction.

Drugs such as Depo-Provera may be used to reduce sex drive and birth control implants, as well as sterilization, are sometimes judicially mandated. Lowering serotonin levels and psychosurgery have been used to curb violence.

Passivity, disorientation, or the inability to flee may be created by sensory weapons. Various citizen protection devices that can be defensively used such as mace fit here, as do nonlethal crowd control devices such as electrical, chemical, strobe, and acoustical immobilizers that disorient, stop, restrain, or block individuals (e.g., Tasers, pepper spray, loud music, flash bang devices, beanbag shotguns, sticky foam released on a floor, straitjackets, and a cage dropped upon or a net fired upon those to be controlled). Spikes in the road may be used to stop vehicles and some cars can be remotely stopped.

Related efforts deal not with the body of the offender but with the instrumentalities involved in the offense. Examples include antidrunk driving interlock systems, which require passing a breathalyzer test attached to the automobile ignition system before a car will start; cell phone muzzling devices for automobiles that use global positioning system (GPS) sensors to prevent the phone from being used while the car is being driven; or mixing a bad smelling chemical into a product to prevent it from being inhaled for its hallucinatory effects. An antipaparazzi device identifies the presence of a digital camera and can then remotely disable it through projection of a light beam.

Note also efforts at redefining the meaning of offender behavior. Thus, treating drug addiction as a medical rather than a criminal problem is in one sense a 'crime' elimination program. In some countries such as the Netherlands, there are safe drug houses where registered heroin users are provided drugs under carefully controlled circumstances. This lessens their need to commit crime to obtain the drugs and also offers a safe environment where they are protected from victimization. A *de facto* policy of toleration and damage control can also be seen in the formal creation of (or winking at) adult entertainment zones ('red light districts'). This can mean greater citizen awareness of victimization risks and some self-policing by service providers.

Exclusion

Potential offenders have traditionally been kept away from targets or tempting environments by exile, prison, curfew, and place or activity exclusions (e.g., restricting the sale of alcohol and cigarettes for juveniles). A related form is the visible warning offered by a stigma such as the brand or clipped ear for offenders in medieval Europe, which encouraged others to stay away. Fear of being degraded and ostracized as a result of stigmatization might also serve as a source of deterrence. Electronic monitoring or location devices based on GPS are contemporary examples. In one form, an alarm goes off and a message is sent to authorities if an adjudicated person wearing a transmitter gets too close to a prohibited person (such as an abused spouse) or leaves (or enters) a restricted area.

Capital punishment is the ultimate form of exclusion. At the other extreme is prevention of birth. With the human genome project completed, neoeugenic modes of exclusion are likely to be entertained. For example, the belief (which ignores interactions with the environment and the socially crafted character of most rules) that DNA is linked to violence and other antisocial behavior could generate another ultimate form of exclusion – requiring a license indicating an 'acceptable' genetic pattern before a child is permitted to be born (*see* DNA, Eugenics). Perhaps a less fanciful example (for the present at least) would be requiring special programs of education and even surveillance for individuals carrying the identified genetic patterns presumed to be associated with the behavior of concern. And with DNA databases, convicted (or otherwise included) individuals, and even close family members can be monitored for future acts.

Offense/Offender/Target Identification

Where it is not actually possible to physically prevent the violation, or where it is too expensive to do so, it may be possible to at least know that it took place and perhaps who is responsible, and to locate where the suspects are and/or where contraband may be stashed (as with X-ray, metal, and chemical detectors).

The goal is to document the violation and identify the violator. A major goal of nineteenth-century forensic science was to develop reliable biometric measures of identity based on the analysis of fingerprints, facial measurements, and mug shots, and chemical properties (Thorwald, 1965). These have significantly expanded from involving a person's gait and voice to tracking their distinctive smell. One technique used by the former East Germany involved identifying individuals by their unique olfactory signature. Architectural designs emphasizing visibility as a deterrent fit here (Newman, 1972), as do video, audio, motion, and heat detection devices and access codes that are presumed to document who enters or leaves an area, or is using a resource such as a computer. Hand-activated personal alarm systems, luggage alarms that go off if a purse or suitcase is illegitimately moved or opened, gunshot detection and location devices, cameras to detect speeders and red light violations, and the electronic tagging of consumer items in stores or books in libraries are other examples.

Hidden identification marks left on paper by the manufacturer or by photocopying machines and identifiers, in material that can be used to make explosives, would be included here. The various 'see something, say something' campaigns, which are dependent on the ease and ubiquity of multipurpose cell phones and e-mail, are a related example. Citizens are encouraged to use hotlines or smartphone apps to report, for example, suspicious persons and objects, erratic highway drivers, drug dealing, poaching, and organizational malfeasance. The police in turn use mass communications media to help identify and locate wanted persons via amber alerts, posting warrant information on Websites and crime reenactments on television, and posing as friends on Facebook pages.

Enhancements to criminal history data systems involving new tools for crime mapping of hot spots and analysis (e.g., Computer Statistics (COMPSTAT)) have appeared and there is increased sharing of information within and between control agencies and between the public and private sectors. There has been a significant expansion of surveillance practices for which there are no, or minimal, specific reporting requirements, as with GPS data, stored communication, and subscriber records (e.g., social media sites, texting, and Web browsing and searching).

Some Other Social Control Dimensions

The above categories are based on combining several aspects, such as whether the focus is on the potential offender, victim, or a resource that is part of the violation, and whether the means literally prevent or simply increase the risks and costs or decreases the attractiveness of violation. Combining separate dimensions into such ideal types can be useful as a shorthand way to classify and compare. Yet this approach can also distort

by merging sources of variation that can be analyzed separately and by excluding other variables.

Another approach starts with single dimensions that may cut across the different forms. Among relevant dimensions are classifications based on visibility or invisibility; openness or secrecy regarding use of the tactic both generally and specifically; control of access into or out of a system; emphasis on an individual, an organization, or a network; a focus on the body, consciousness, or the environment; reliance on machines, humans, or both; normative or nonnormative influences and, if the former, whether they involve criminal or civil law, policies, or manners; relative costs of a tactic including errors and mistakes; reliability and validity and ways of determining such costs; the presence or absence of democratic decision making, and review processes regarding the adoption and application of a tactic; and whether the goals of subjects and agents are the same, or at least overlap, or are in conflict. While all technological control efforts have elements in common, those involving dissensus and inequality are particularly important because of the centrality of human rights issues and the prominence of control and countercontrol efforts.

Some Social and Ethical Implications

Whether dealing with questions of justice, quality of life, security, health, the environment, or other issues, the potential benefits of science and technology are hardly deniable. In the case of criminal justice, for example, Clarke (1997) documents a number of successes. Yet given the sense of urgency about many problems and what is often the self-justifying tunnel rhetoric of those offering solutions, caution is needed, as well as midterm corrections, limitations, or prohibitions. To argue for a yellow light is certainly not a call to cease innovation or the search for better solutions.

However ideal a technical control system may appear in the abstract under ideal laboratory conditions, or however successful it may be in the short run, the world of application is often much messier and more complicated than the public relations efforts claim. There is rarely a perfect, or cost-free, technical fix (if nothing else, a given choice is likely to involve using resources that might have gone elsewhere). The technology's narrowing of focus on a given problem may come at the cost of failing to see larger systemic contexts, alternatives, and longer range consequences. The complexity and fluidity of human situations makes this a rich area for the study of trade-offs, irony, and paradox. Goal conflicts, unintended consequences, and sources of neutralization are among the factors limiting technical efforts to ensure conformity, as discussed below.

Goal Conflicts

At an abstract level, consider the possible tension between values. In the case of the new supermaximum security prisons, there is an enduring tension between the values of custody and punishment, as against care and some form of rehabilitation (Rhodes, 2004). More intensive mechanical control, whether within the prison or the community, often comes with a diminution of human contact and help with efforts to overcome the social and personal deficits that contribute to violations. Short-term gains in control may come at a cost of longer term losses (Byrne et al., 2007).

Informing subjects that a technique is in use is intended to serve the goal of deterrence, but such information may in turn serve as a strategic support for clever rule breakers who will then seek ways around it.

The expectation that one should be judged as an individual and in context may conflict with the greater rationality and predictive success believed to be found in categorical responses based on aggregate data and models divorced from the richness of particular situations. An automatic process that eliminates the misuse of authority and appears to offer fair (as in universal treatment) can conflict with the need to respond to the uniqueness of particular contexts. The latter requires discretion to potentially override action by a machine unable to take account of the concrete variation of the situation.

More concretely, goal conflicts in immediate situations can be considered. Thus, barriers need to prevent uninvited parties from entering a private space, while enabling those within such a space to leave in case of emergency. For example, bars over windows designed to keep out thieves may also prevent occupants from escaping through the window in the event of a fire. Conversely, barriers intended to keep persons or animals contained within a facility may lead to their being unable to get out when there is a fire (e.g., in a prison or a horse stall).

In commercial settings where access to merchandise is important, attaching expensive clothes (e.g., leather jackets) to a rack with a locked cable reduces the likelihood that an item will be stolen, but it also complicates trying clothes on and impulse buying. Encryption of information offers security, but at a cost of increased expense, slowing down the time required for a transaction and the risk of losing the key.

Unintended Consequences

Situations involving unexpected and unwanted results offer a rich area for analysis (Merton, 1957; Sieber, 1982; Marx, 1981; Tenner, 1997). It may be difficult to limit the impact of a technology. Terms such as blowback, collateral damage, spillover, backfire, and overshooting the target capture this. Techniques that immobilize suspects may do the same for control agents (e.g., sound wave technology intended to cause suspects to lose control of their bowels and a slippery banana peel substance that makes it difficult to walk). Uncontrollable wind patterns may send tear gas to places where it is not directed (including, literally, blowback on users). Consider the fact that enhanced lighting and lines of visibility can help perpetrators identify victims or control agents, as well as the reverse. The roads used by the Roman legions venturing forth to conquer became equally available to other conquerors who later marched on Rome. President Nixon, in an effort to secretly tape others famously also taped himself, leading to his downfall. Conversely, a protective device can lock everyone out when the keys are lost. The removal of benches from public areas denies the homeless, as well as others, a place to sit.

Automatic processes can result in punishment without trial. For example, *The New York Times* (28 December 1989) reported that a thief in Mobile, Alabama, was killed in a trap set by a homeowner. The trap consisted of two hunting rifles placed in

separate locations. One pointed down a staircase. The rifle fired when the thief stepped on a wire rigged to the trigger. A neighbor called the police when he heard a shot fired and then entered himself. It is easy to imagine good Samaritan scenarios that end disastrously (e.g., a passerby who is shot by a home-made burglar alarm after seeing a fire and rushing in to help).

Second-order effects also may occur. For example, when initially used, barrier strips intended to stop fleeing cars almost instantly released the air in the tires, sometimes causing high-speed crashes. Persons publicly identified as sex offenders may face vigilante attacks. The death of 30 persons in a fire in the London King's Cross subway station was attributed to fumes from antigraffiti paint. Enhanced technical enforcement along the United States–Mexico border has led to a funnel effect in which immigrants seek to enter through more dangerous desert areas with an increase in mortality (Cornelius, 2001).

An intervention may interact with other conditions to produce an undesired outcome. Thus, pepper spray is intended as a nonlethal alternative, but may be fatal to those with severe asthma or other respiratory problems. Consider also the warnings to pacemaker users that electronic sensors are in operation in retail settings. Will a nonlethal antitheft device that delivers a 50 000-V shock be lethal to the driver of a stolen car with a weak heart?

Moreover, there may be longer term health consequences that are not immediately visible. Questions have been raised, for example, about the effect of repeated exposure to radiation from X-ray search machines, particularly for children, the pregnant, and agents with repeated exposure (as reported in *The New York Times*, 26 April 2012).

Displacement

Several forms of displacement can be noted involving place, time, type of offense, and offender (Reppetto, 1976; Norris et al., 1998). Issues of displacement are central to many control settings where there are conflicts of interest and where rule breakers who have some resources find ways to beat control efforts.

The commercialization of protection, such as with embedding a hidden transmitter in cars that permits it to be located by remote electronic activation or gated communities to keep out would-be thieves, may lead to greater victimization of others who are unable to afford such enhanced levels of security.

Derivative offences may appear. The discovery that a target has been rendered useless to an offender may increase violence, whether as a resource to gain the needed access, or out of frustration. For example, the appearance of 'carjacking' is related to more sophisticated antitheft devices on cars. The use of access codes to activate autos and appliances may mean that the crime of burglary is converted to robbery or kidnapping when thieves confront property owners and demand not only the property but also the code to make it work. A frustrated thief may respond to a self-destruct automobile radio by fire-bombing the car.

New secondary laws that criminalize the possession of artifacts or activities designed to thwart enforcement may develop. Consider laws prohibiting the production, distribution, and use of products intended to falsify drug tests or for the possession of a radar detector designed to thwart traffic enforcement. In such cases, the guilty face charges for the secondary offense of possession, even when they were not committing the primary offense.

Neutralization and Escalation

Whether out of self-interested rule breaking, principled rebellion, or human contrariness, individuals can be very creative in neutralizing systems of control. In a free market economy, new controls create incentives to develop means of neutralization. This may lead to a higher level of play without fundamentally altering the game. A dynamic struggle may escalate, for example, when police use body armor and offenders react by using more powerful weapons and wearing armor themselves.

The fact that locks open with keys and borders require access points means they are eternally vulnerable. Marx (forthcoming) identifies a number of *behavioral techniques of neutralization* – strategic moves through which subjects seek to subvert controls. Reverse engineering permits a *breaking* move. For example, not long after antitheft ignition protection systems appeared on automobiles, a device that permitted bypassing the lock became available. No special tool is needed to spray paint over the lens of a video camera. In a *distorting* move, the initial antidrunk driving car interlock systems can be beaten by saving air in a balloon or by having someone else blow into it to start the car. A variety of moves can be seen in efforts to defeat urine drug tests. These range from contaminating the sample by pouring bleach on one's hand to the *switching* move of using a catheter to insert drug free urine into the body. *Discovery* moves are illustrated by a driver's use of radar detectors to locate police radar. When systems cannot be defeated technically, such as with sophisticated encryption technology, then their human context may be compromised, whether through coercion, corruption, or deception. For example, a thief who was unable to break a manufacturer's sophisticated encryption code, nevertheless managed to embezzle millions of dollars through generating fake invoices. He did this by having an affair with the individual who had the decryption codes.

In many settings, subjects have some rights and are entitled to challenge specific technological control. One thus sees *explanatory* moves through which an unfavorable result is reframed in an acceptable way by offering alternative data and citing the claims of rival experts, or making claims about rights and procedural violations. An *empirically valid* result does not guarantee a *socially meaningful* result. Thus, a DNA match between material from a crime scene and a suspect cannot reveal if the death in question resulted from a homicide or self-defense. Even when there is no question that a homicide occurred, the sample might have been planted or the evidential chain of custody may have been compromised. A computer match between persons on welfare and those with bank accounts may reveal a person whose account exceeded the savings limit, but such data do not provide proof of *cheating* since funds may have been held in trust for a funeral – a contingency that is legally permitted, but not necessarily built into the computer program. Audio and video recordings may reflect what was done and said, but may not reveal why, or what a suspect intended. Seeing should not automatically mean believing. Thus, a suspect in an undercover scheme may

have been threatened or entrapped off-camera. Nor does a drug test, even if 'valid,' indicate the presence of drugs within a person's system, a necessary indication of a violation. Depending on the assessment used, if the standard is set low enough it is possible to have a 'false-positive' reading as a result of just being in a room where marijuana was smoked or the result may be as a result of medications or eating certain foods.

Some Additional Factors

The overselling of technical solutions may exaggerate the risks, engendering immobilizing fear and leading to an unduly suspicious and distrustful society as well as wasting resources. Alternatively, an unexamined faith in a tactic's supposedly failsafe nature can lead to complacency and a false sense of security in which individuals are lulled into not taking necessary precautions. Consider a Los Angeles case in which a man sentenced to house arrest and required to wear an electronic surveillance bracelet shot and killed his estranged wife. She had not reported his threats to police because she thought she was safe as long as he had the bracelet on.

The seemingly ever-greater ease and efficiency offered by technological means can conflict with traditional liberty-protecting ideas of reasonable suspicion, minimization, and impracticality. Of course, as a folk expression holds, "if you hang them all you will certainly get the guilty." Risk prediction technology, as in the case of profiling, may be statistically accurate across many cases, but inaccurate with respect to a given case (this is the issue of aggregate rationality vs. individual cases). Even if accurate in an individual case as a prediction of future behavior, it may conflict with the individual's expectation to be judged on the basis of actual behavior.

Improvements in the ability to identify rule breaking may vastly expand the pool of 'suspects' who are subject to social control. Control systems may become overloaded, which can lower morale among enforcers who feel overwhelmed or offer corruptible officials a resource (nonenforcement) to market. Since resources for acting on all the available information may not be at hand, authorities may face charges of discriminatory enforcement.

Even when adequate resources for full enforcement action are available, organizational effectiveness can be harmed. Automatic technical solutions developed without adequate appreciation of complexity and contingency run the risk of eliminating the discretion, negotiation, compromise, and informal understandings that are often central to the morale and effective working of organizations (Dalton, 1959; Goffman, 1961). By broadening the documented pool of violations and violators, authorities may feel compelled to take action in cases that they otherwise think should be ignored. The rigidity of the machine and limited possibilities for immediate innovation can be damaging. One strand of humor involves the automatic, unthinking, and repetitive quality of many mechanical devices (such as in the classic Charley Chaplin film *Modern Times*).

If technical solutions were somehow to be effective at eliminating all rule breaking (leaving aside the conflict between, and the ambiguity of and lack of consensus on, many rules), such systems would risk becoming unduly rigid. Much innovation is initially seen as deviance. Experimentation and risk taking require latitude and can be aided by anonymity and secrecy. A socially transparent, engineered society would be more orderly, but likely less creative or dynamic and less able to respond to changing conditions.

If order depended only on technical means of blocking infractions, rather than on legitimacy, how would people behave if such technical means failed (e.g., in the case of a power failure and a failure even of backup systems)? A social order based primarily on technical fixes is likely to be as fragile over time as one based primarily on overt repression.

Even if systems could somehow be made fool- and fail-proof, with ever more advanced technology, there is a danger of viewing humans as robots, rather than as creative beings capable of making choices about how to behave. The former image is inconsistent with belief in the dignity of the autonomous individual in a democratic society. Whatever a technology is capable of, the view of humans as volitional (and hence responsible for their behavior) and beliefs about the inviolability (absent clear justification) of the borders that protect private personal zones around the human body, mind, relationships, communications, physical space, and past history are central to ideas of respect for personhood. The tools we use to communicate say something about how we see human beings and what kind of a society we live in and seek to create. Symbolism matters. So do precedents.

With new and seemingly effective social control techniques it is important to ask, "where might this lead and what kind of a society is being created?" In the United States, a future radically at odds with the nation's higher ideals is not likely to come about through cataclysmic change, but gradually in a thousand little ways, each perhaps understandable (if often aided by fear or seduction). In totality, however, such small changes can create a very different world – a world arrived at through accretion under the radar, rather than through full public dialogue.

The search for stand-alone mechanical solutions also avoids the need to ask why some individuals and groups break rules, and it points away from examining the social conditions that may contribute to violations and to the possibility of changing those conditions, rather than only trying to change the individual. Technical solutions seek to bypass the need to create consensus in a community in which individuals act responsibly as a result of voluntary commitment to the rules, not because they have no choice or fear reprisals. This emphasis can further social neglect and subsequent problems, leading to calls for more intensive and extensive reliance on technology in a seemingly endless self-reenforcing spiral.

There is a magisterial, legitimacy-granting aura around both law and science (Ericson and Shearing, 1986). Technological controls, presumed to be science based, are justified as valid, objective, neutral, universal, consensual, and fair. Their legitimacy may be strengthened in free market societies where such tactics often can be used by citizens (e.g., video cameras to record police behavior or DNA analysis offered by criminal defendants) and internally by police managers for guarding the guards.

Yet tools are socially created and their results are socially interpreted and thus potentially disputable. They exist in dynamic interdependent systems where interests may conflict, inequalities are often present, and where full impacts may be difficult to envision. Critical inquiry and humility are as needed, as are innovation and experimentation. It is important to maintain, if not a doubtful attitude, at least a respectfully skeptical attitude toward claims for the new; at least until they are examined both empirically and morally.

Our age has two rather distinct fears of technology. One, a la George Orwell, is that it will work all too well, creating a manipulated, totalitarian society naively taking pride in how free it is. The other fear, reflective of Franz Kafka, is that it would not work well enough. This suggests a crazily complex, out-of-control, interdependent, opaque society steeped in technological errors and *Catch-22* absurdities.

A well-known, if often naïve, expression (given that individuals and groups do not start with equivalent resources) holds that where there is a will there is a way. This points to the role of human motivation in obtaining goals. However, in light of the control possibilities made available by science and technology, this slogan can be reversed to "where there is a way there is a will."

The myth of Frankenstein implies that one must be ever vigilant to be sure that one controls the technology rather than the reverse. As Jacques Ellul (1964) argues, there is a danger of self-amplifying technical means silently coming to determine the ends, or even to become ends in themselves divorced from a vision of, and the continual search for, the good society.

Technology Assessment

Arie Rip, University of Twente, Enschede, The Netherlands

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Technology assessment (TA) refers to the early identification and assessment of eventual impacts of technological change and applications, as a service to policy making and decision making more generally. TA can be done by (or for) business firms, or as a medical, social, or environmental impact assessment. Its main use is in the public domain, and includes parliamentary TA. Recent developments include public participation and involvement in innovation processes (Constructive TA). Since the 1980s and 1990s, public service TA has professionalized and articulated specific methodologies for that domain. But TA is also part of broader developments such as the emergence of a risk society.

The term 'technology assessment' (TA) has a variety of usages. The main meaning is the early identification and assessment of eventual impacts of technological change and applications, performed as a service to policy making and decision making more generally. The term TA also is used when firms, consultancies and technological institutes, agencies in health care and other social sectors, attempt to assess the promise, and potential profit, of new technological options, and/or perform a broad version of cost-benefit analysis, sometimes also including risks. In both cases, TA includes efforts to anticipate future developments (of technology, and its relations with markets and society), and it also involves the feedback of such anticipations into relevant decision arenas. This combination is the defining characteristic of TA exercises.

Context

Practical and political concerns with the uncertainties involved in developing and applying new technologies were the breeding ground for TA in the 1960s. One response to these concerns was an attempt to manage the uncertainties through a combination of technological forecasting and the development of techniques to address and evaluate impacts. US organizations like the RAND Corporation pioneered such TA techniques. This managerial response sometimes was broadened to include wider societal impacts; for example, the impacts of the US space program were explored by making comparisons with the impact of the railroad on American society.

The other response was policy-oriented and political, taking the emerging concern about the negative impacts of technology, for example, on the environment or in relation to defense and security issues, as a starting point for attempts to evaluate such impacts at an early stage. Ways to do so included the techniques developed as part of a managerial approach, but also were able to build on policy analysis and on action-oriented research.

Special agencies were made responsible, or even created, for such a task, as when in 1970 in the USA, a federal law established a Congressional Office of Technology Assessment (OTA), as "an aid in the identification of existing and possible impacts of technological application." Congress also was interested because such analytical support would increase its power vis-à-vis the Executive Branch. The example of OTA was noticed in European countries, and parliamentary TA agencies also were established there, after some delay, the specific format depending on the political tradition of each country.

By the late 1980s, TA was a recognized activity, professionally (cf Porter et al., 1980) and politically. Gradually, the earlier and almost exclusive emphasis on analytic approaches and the production of reports was complemented by an interest in linking up more closely with decision making, or at least contributing to setting an agenda. Public debates about energy and environmental issues helped give more prominence to this aspect of TA.

By the 1990s, a philosophy of TA had become widely accepted (even if it was not always formulated explicitly). This philosophy stressed the importance of anticipating impacts and giving feedback into choices and decisions, in order to reduce the human and social costs of learning how to handle technology in society, as compared to when this happens through trial and error. The experience of a series of chemical and nuclear accidents, as well as the uncertainties about the new biotechnology (and life sciences more generally), since the mid-1970s, contributed to the legitimacy of attempts to anticipate and avoid errors, up to disasters. This philosophy covers what would otherwise appear to be a wide variety of approaches, ranging from *technology forecasting* to *consensus conferences*. The philosophy is also visible in discussions about *technology policy*, when it is suggested that technology policy should include a strong TA component. Actually, in the 2000s, government policies on genomics and nanotechnology to an extent do incorporate TA, including attention to ethical, legal, and social aspects and so-called upstream public engagement.

Main Strands in the Variety of TA Approaches and Activities

At least since the 2000s, five strands of TA can be distinguished, each with its own style and addressed to different audiences:

1. TA in firms and in technological institutes, oriented toward mapping future technological developments and their value to the firm or institute, and used as an input in

strategy development (Hastbacka and Greenwald, 1994). 'Picking the winners' (or 'avoiding the losers') used to be the overriding orientation. This strand of TA has developed relatively independently of 'public domain' TA, but links are emerging because of the need of firms to take possible societal impacts and public acceptance into account. The *biotechnology* sector by the late 1990s recognized this because of the impasse about genetically modified organisms in agriculture. Thus, the 'insiders' are now interacting with the 'outsiders,' and the effect is that prudent firms are receptive to public-interest assessments.

2. TA in specific sectors, like environment or health care and regulation, as an instrument to determine acceptability of a project, new product, or technological option, in relation to the public interest in, and policies about, that sector. Environmental impact statements are now required in many countries before projects can be implemented (Vanclay and Bronstein, 1995). Medical and health care TA is a recognized specialty with its own international society and meetings, focusing on evidence-based evaluations of concrete medical and health care activities and options (cost-benefit analysis, risk analysis), not on wider societal impacts.
3. TA for policy development and political decision making about projects or broad programs with a strong technological component (for example, the electronic superhighway or modern agriculture) or important technologies (for example, genetic modification). One can call this 'public service' TA, and consider the US OTA (abolished in 1996) as the embodiment of this type of TA. OTA, during its lifetime, developed a robust approach to TA studies (see Wood, 1997). Other TA bodies that serve national parliaments and/or national governments now sometimes include participatory TA methods in addition to expert-based approaches.
4. TA exercises can be oriented to the public arena more generally, with a focus on articulating and building an agenda for handling new technology in society. This strand is influenced by the increasing calls for *participation* (at least by so-called new stakeholders like environmental groups). While it is particularly visible and more or less institutionalized in European countries like Denmark and the Netherlands, participatory methods such as consensus conferences have been taken up all over the world. *Agenda-building* TA has a longer history, however, given that controversies over new projects or new technologies (and studies and documents produced in the course of such controversies) induce learning about potential impacts and articulation of the value of the technology. Agenda-building TA thus merges with informed consultation processes to reach agreement on the value of new technology. The implication is that there is overlap between TA and more general political and policy approaches for articulation and learning.
5. A further strand of TA, which can be called bridging TA, aims to bridge the distance between ongoing innovation and anticipation of social aspects and impacts, and to do so in real time. In Constructive TA (CTA) (Schot and Rip, 1997), it is recognized that the impacts of new technology are jointly produced by the technology, the actors involved, and wider interactions. This strand of TA leads to exercises in coconstruction of technology development and its embedding in society with different stakeholders for older as well as newer technologies. Independent of CTA, such activities were already taking place when the introduction of new information and communication technologies, both within and between organizations, was broadened by having more user involvement in design. Real-time TA (RRTA) (Guston and Sarewitz, 2002) uses a variety of tools and approaches to anticipate and deliberate interactively. Both CTA and RRTA have developed sociotechnical scenario methods to address newly emerging technosciences like nanotechnology. Societal experiments with the introduction of new technologies, such as electric cars, which involve both private and public actors, are occasions for learning about new technologies, and can be seen as a further version of 'bridging' TA.

It is clear that, over time, the first three strands, all of which are strongly professionalized, have been complemented by broader strands focusing on interaction, deliberation, learning, and agenda building. Possible next steps will be discussed in the concluding section.

Methodological Issues

Earlier, methods of TA emphasized data collection and analysis about present impacts and trends. They also may involve counterfactual speculation, consultations of experts to assist with the refinement of the results, and/or the construction of sociotechnical scenarios. By now, the toolkit of TA contains a wide variety of tools, ranging from forecasting supplemented with social and sociotechnical mapping, multicriteria analysis and integrated assessment, to mediation and communication techniques. The selection of appropriate tools is often eclectic, related to the sponsor and domain of the exercise: private/promoter, sectorial/regulator, public policy, or the public domain more generally. While there are recognized TA professionals, TA exercises are carried out by a wide range of consultants, academics, members of dedicated agencies, their committees, and volunteers.

The combination of anticipation and feedback, characteristic of all varieties of TA, entails a methodology that combines writing a history of the future, supported by judgments of experts and by social science insights and data, and informing action or preparation for action. Relevant social science insights derive from the sociology and economics of technology and innovation, and organizational sociology, but also general sociology and political science. A key notion is the coevolution of technology and society. Estimating impacts is speculative, of course, but the speculation is controlled by data, scholarly insights and experience. Uptake into action remains precarious, exactly because of the fallibility of such estimates: who could have predicted the further development and impact of the Internet in the early 1990s? On the other hand, efforts at foresight can be productive even when they turn out not to be correct, because they stimulate joint learning.

In the literature, a fundamental dilemma has been identified, which is called the anticipation and control dilemma (Collingridge, 1980). At an early stage of technology development, the nature of the technology and the articulation of

interests in it are still malleable, but it is unclear at that stage what the effects and impacts will be. By the time these consequences become clear, the technology is entrenched and vested interests make it difficult to change it. If the technology turns out to be undesirable, as happened with the pesticide DDT, the only possible response then is to forbid further deployment of it. More is possible, however, than in this stark version of the control dilemma.

A generic strategy to avoid such decision regret is to keep flexible for as long as possible, at the risk of failing to pursue any of the various options for sufficiently long to see what they may be worth. An interesting example of such a flexible strategy is the 1991 French Law on nuclear waste handling, which requires three options to be maintained for a period of perhaps 15 years, and with annual public evaluation of progress and prospects. The Parliamentary *Office d'évaluation des choix scientifiques et techniques* is involved, and, over time, modifications can be made to the trajectories. (Further background considerations are offered by Callon et al., 2009.)

Recent research in the economics and sociology of technology has shown how path dependency occurs over time in technological development, and how coproduction of impacts is shaped in those paths. The QWERTY keyboard of typewriters, and now also of computers, is a well-known example of path dependency. Path dependencies can be seen as a problem for TA, because they reduce flexibility to go into more desirable directions. But understanding the dynamics that generate path dependency allows better anticipation of future developments, as well as identification of opportunities for them to be modulated to some extent (Garud and Karnøe, 2001).

Situating TA in Contexts, and Future Directions

Government technology policy most often focuses on promotion of (selected) technologies. The main question for such technology policy is to 'pick the winners' now for society as a whole. Their actual development requires anticipatory coordination, in which versions of TA (particularly 'bridging' TA) can contribute. This is what one can see happening in the European Technology Platforms stimulated by the European Commission. On the other hand, other agencies of the same government may be occupied with reducing the human and social costs associated with the introduction of new technology, for example, through occupational health, safety and environmental regulation. This conflict between promotion and control of new technology is characteristic of the way modern societies have come to handle technology. It is not only reflected in the division of labor between government agencies, but also in cultural and political views, as in the assumption that there will be proponents and opponents to any given new technology (Rip et al., 1995). Earlier, TA was liable to become a victim of such conflicting views when technology promoters condemned TA as harassment of progress. While contestation will continue, there is now more interest in constructive approaches. And there is a move, starting with nanotechnology, to ask promoters of new technology to become proactive in taking possible impacts into account. In European policy discourse, this move has acquired its own acronym RRI, for Responsible Research and Innovation (Fisher and Rip, 2013).

One key point, related to divisions of labor in modern society, is the asymmetry between 'impactors' (those at the source of impacts) and 'impactees.' The asymmetry can be due to a difference in power, but it also always involves a difference in timing. Initiators of technological development know more, and have invested more, at an early stage, and impactees and TA agents have to wait and, in a sense, follow their lead.

The asymmetry has another component: technology developers are 'insiders' and do not necessarily know very much about what happens on the 'outside' after a technology is developed. Adoption and diffusion, however, are up to 'outsiders' who typically have different knowledge, interests, and expectations than developers. The story of nuclear energy, since the 1960s, is in part a story of a struggle between insiders and outsiders. At a much smaller scale, the same storyline is visible in the development of cochlear implants for deaf people, where it turned out – unexpectedly for the insiders – that sizable factions of the deaf community were very negative about taking congenitally deaf children out of the sign-language culture of their deaf parents by providing them with implants (Reuzel, 2004).

Another key point is about cumulative effects of living in a technological society. Risk repertoires have emerged in which the impacts of new technological developments are treated similarly to those of earlier technologies. In the 1970s and early 1980s, the risks of recombinant DNA research were imagined in terms of scenarios of runaway organisms and addressed with probabilistic risk analyses, exactly as previously had been accepted for runaway accidents in nuclear power plants. Accordingly, the measures that were promoted focused on containment. A similar conception of risk is visible in concerns about engineered nanoparticles.

Anticipation and feedback occur all the time. Early warnings of hazards and controversies over new technologies are examples, and may be starting points for TA exercises (cf Harremoës, 2001). We live in a *risk society* and modernity has become reflexive (Adam et al., 2000). The rise and subsequent broadening of TA is then an indicator of *reflexive modernity*, and a conduit to enhance reflexivity – while also chaneling it in certain ways. There were criticisms of the instrumentalization of reflexivity and possible technocratic tendencies of TA in the 1970s and 1980s, as well as of the symbolic nature of participatory TA exercises in the 1990s. These tendencies are still present, but TA practitioners now are more conscious of them.

A further development is the increasing acceptance of the so-called *precautionary principle* (since the Rio Declaration of 1992): regulatory action is justified even if there is not yet conclusive evidence about risks, or negative impacts more generally. Precaution is actually predicated on speculative scenarios about what might happen, and TA can offer quality control of such scenarios.

Clearly, TA is not just a new professional and managerially oriented activity (since the late 1960s) and an approach to interactive agenda building (since the late 1980s). It is part and parcel of larger developments, and may need to develop further in order to contribute to the challenges involved (Rip, 2012). What is happening anyway is the increasing involvement of ethicists in TA, which is important but can also lead to a reduction in complexity if principle-based ethics and checklist approaches are followed. There is also the increasing interest in what has been called 'strategic intelligence' about technology in society, for

which TA would provide one of the inputs. The notion was developed in the context of technology policy (cf Kuhlmann, 2003), but its use is broader, since all sorts of actors, including civil society organizations, are interested in such strategic intelligence. TA will then become a pervasive feature of late modern, reflexive society, rather than a dedicated professional practice. The professional input will remain important, however, to allow for quality control.

Abstract

An evolutionary approach to the history of technology starts from the position that technologies change as a result of processes of 'descent with modification' in Darwin's famous term; it is in this sense that technology is cumulative. Taking this perspective makes it possible to go beyond the tautology that superior technologies spread because they are superior. It introduces a range of transmission mechanisms with different consequences and an array of different forces that affect what is transmitted. These are described and their implications are illustrated by means of examples.

Introduction

The study of technology is a field in which evolutionary ideas have been current for many years, since the idea of a kind of Darwinian competition between different means of achieving the same practical ends is one that seems obvious, and indeed has been very fruitful. However, when we start trying to implement an evolutionary approach more rigorously it turns out to be more complex than we may initially suppose. Indeed, one of the important benefits of taking an evolutionary perspective is that it goes beyond relatively simple ideas of competition and technological improvement, introducing a range of other forces whose impact is not often considered. In this, it meets the requirements for any worthwhile approach to technology: first, to go beyond the tautology that superior technologies spread because they are superior; second, to account for the fact that while the history of technology is famously cumulative, in that innovations build on the continuing existence of features that have resulted from earlier innovations, the process can also go into reverse; and third to account for the fact that, "people in even the simplest human societies depend on tools that are beyond the inventive capacity of individuals" (Boyd et al., 2013: 120), the technologies of the Inuit in the Arctic being a famous example.

In what follows I will first outline the framework adopted here for viewing technology from a Darwinian evolutionary perspective as a domain characterized by the generation of variation, by mechanisms for its inheritance, and by selection and other mechanisms that affect differentially what is transmitted through time, leading to 'descent with modification'. I will then outline a number of studies that illustrate these different processes and address the question of whether an evolutionary theory of technology does indeed meet the requirements listed above.

What Evolves?

There are many different definitions of technology. For example, Lemonnier (1992: 1) proposes that technology "embraces all aspects of the process of action upon matter, whether it is scratching one's nose, planting sweet potatoes, or making jumbo jets", while Mesoudi et al. (2013) define it as "goal-oriented shared knowledge together with its external means. It is thus knowledge geared to, and organized around, solving specific problems faced by a group or society". The definition preferred here though is that of Arthur (2009), who defines a technology as "a phenomenon captured and put to use". This avoids the suggestion of teleology present in the previous definition. Inventions need not be made in the context of solving problems but may occur more or less by chance in the context of activities unrelated to the domain in which they subsequently turn out to have an application. Moreover, even in apparently very simple areas of activity there will often be a variety of different ways of putting a phenomenon to use. The French anthropologist Marcel Mauss noticed in World War I that French and British soldiers had different types of spades and shovels for digging trenches and were unable to use each other's tools effectively because they involved entirely different kinds of bodily movement (Mauss, 2006[1935]).

Whatever the definition though, the key question for any Darwinian approach to technology is, what are the things that are subject to 'descent with modification'? The answer in terms of the definition adopted here is that the entities that are the subject of variation, inheritance, and selection processes are technological lineages, recipes for techniques, routines, and practices linked by ancestor–descendant relationships (O'Brien et al., 2010), that capture and put to use specific phenomena in particular ways, based on specific areas of knowledge. Thus, ceramic vessels, for example, put to use one set of principles to make containers but barrels or plastic bowls make use of very different ones. A lineage, or rather several different initially independent lineages, of techniques or practices for the production of ceramic vessels can be traced for thousands of years up to the present. Plastic vessels put to use very different phenomena requiring the application of techniques and practices that have their own lineages in the history of the chemical industry. The replacement of ceramic vessels by plastic ones in some domain represents a replacement of one lineage by another, but we should not automatically assume that this means it is superior; such a claim requires testing in relation to alternatives. Indeed, it cannot be emphasized too strongly that an evolutionary theory of technical change does not require inevitable increases in superiority.

The Processes of Cultural Evolution

Variation in techniques and practices is generated by invention, which may involve the appearance of some novel traits or

novel combinations of traits that exist already (Lewis and Laland, in press, Enquist et al., 2011). It may simply represent unintended copying error but may also involve trial-and-error experimentation. However, there is no guarantee that goal-directed experimentation will result in a superior outcome, as the history of failed inventions shows. The concept of invention is common to all approaches to technology. What is distinctive of the evolutionary approach is the wide range of forces that are postulated to affect the transmission of the invention once it has occurred. In the case of technology, as with all aspects of culture, the transmission mechanism is social learning: people learn ways to think and act from others. Of course, the routes through which culture is transmitted are much more diverse than those for genes (Cavalli-Sforza and Feldman, 1981), and different routes, for example parent to offspring or teacher to class, have different consequences for the patterning of cultural change through time. It has also been shown that the processes of social learning themselves are varied, with some leading to greater fidelity in transmission than others, imitation and teaching in particular (Dean et al., 2012; Kline et al., 2013).

If no other forces are acting on what is transmitted ('unbiased transmission') then the relative frequencies of the different technological variants ('ways of doing') in the population after transmission will in principle be the same as before, except that in any finite population some variants will be copied slightly less often and some slightly more, purely by chance. Perhaps surprisingly, this 'unbiased' process will have major effects on the frequencies when it is repeated many times, leading to the disappearance of some variants and to others attaining high frequencies even when variants are functionally equivalent (see Bentley et al., 2004 for a worked example). This is the cultural equivalent of genetic drift. It can easily be appreciated that in these circumstances any invention appearing for the first time will have a high probability of disappearing almost immediately, even if it is potentially useful. However, in many cases there will be other forces acting. One is natural selection, in the sense that those individuals who inherit or acquire certain technological attributes may have a greater probability of surviving and/or reproducing than would those who do not; this process will continue, leading to their increased prevalence, so long as those possessing the attributes pass them onto their children. For example, in many parts of the world, adopting an agricultural rather than a hunting-and-gathering way of life clearly led to greater reproductive success (though not to better health (Lambert, 2009)), reflected in the fact that it led to increased population densities; as a result, the technical traits that characterize agriculture spread and, in some cases, subsequently influenced genetic evolution (e.g., the ability to digest lactose: Bersaglieri et al., 2004).

In addition to selection, a number of what have been termed 'bias processes' (Boyd and Richerson, 1985) can affect whether inventions are transmitted; these refer to factors that affect what and who people try to copy when they are learning from others. Thus, 'results bias' refers to the situation where people look at what other people do, for example, the crops they plant, compare the results with what they are doing themselves, and then change what they do because the other way of doing things seems to be more effective. 'Content biases' are affected by features of transmissible phenomena that make them intrinsically more or less memorable. 'Context biases' are aspects of the context of learning that affect what is transmitted; thus, something may be copied simply because the person initially doing it is prestigious ('prestige bias') or because it is what most people locally do ('conformist bias'). In these latter two cases, whether a particular technical attribute or practice that becomes more prevalent in a population has nothing to do with its intrinsic properties as such but only with the context of learning, though with the underlying assumption that adopting such a decision rule is likely to be a good one in practical terms where there is less clear evidence one way or the other about which of a set of variants is superior. It is worth adding that even technologies that are beneficial in cost–benefit terms are not immune to chance loss, drift effects, when populations are small, as shown by Rivers (1926) for canoes in one of the Pacific islands (and see below).

Finally, it is important to be aware that particular technical skills and practices that are favored by selection and bias processes at a given time will not necessarily continue to be favored if there are changes in aspects of the external environment, including humanly induced ones, even if they are not directly connected to the skills themselves. They are then likely to be vulnerable to loss. Thus, Reyes-García et al. (2013) have shown that the loss of indigenous knowledge of wild-plant use among the Tsimane, an indigenous group in Amazonia, is greater among men than women and among those who live nearer towns. They suggest that this may be because such knowledge is increasingly irrelevant in the new socioeconomic and cultural conditions in which people find themselves.

Technological Lineages and Human Populations

A key point to reiterate here is that the object of the evolutionary analysis of technology is technological lineages, not human populations, and because they are reproduced in different ways there is no reason in principle that they should run in parallel even though they are obviously linked. Thus, to understand trajectories of technological change we need to do two things: (1) we have to address histories of technologies; (2) we have to examine the histories of the human populations through which they are transmitted. With regard to the first, it is necessary to identify histories of technological transmission to show that an ancestor–descendant relationship exists, if indeed it does. Continuities or discontinuities through time may simply reflect contingently optimal responses to stable or unstable local ecological conditions. In any case, assuming that a real technological lineage has been identified, we must then attempt to understand the forces shaping it. Second, we need to independently understand the histories of the *relevant* populations (see below). The possible linkages or feedback loops between technologies and populations are many and varied. A technology may or may not have a positive effect on the survival and reproductive success of a human population while replicating successfully itself. Even if it does, its effects may be overwhelmed by other factors, such as the extinction of the population for other reasons. If a technology is vertically transmitted with respect to its human population (i.e., from parent to child) then it may be particularly vulnerable in this respect. It perhaps goes without saying that few if any studies

have taken all these different elements of the evolutionary analysis of technology into account (for recent proposals on how to approach this complex problem, see Beheim and Baldini, 2012; Mesoudi et al., 2013: 202–204).

Invention and Innovation

Some inventions are relatively obvious and have therefore been made again and again. For example, it seems that wherever in the world people came to depend to a significant extent on collected seeds for food, they invented and used grinding stones, since these are very effective tools for processing seeds into food and the cost of producing them is far outweighed by the subsequent benefits gained. But it is by no means necessarily the case that the appearance of new conditions will result in inventions that take advantage of them.

In this connection, it is worth referring to Perkins's (2000) contrast in the space of technological search between 'Homing spaces', where there is a clear gradient pointing toward a viable outcome, and 'Klondike spaces', where high-yield nuggets are sparsely distributed and there are few signs to indicate when you are near one of them. This idea may be linked to the metaphorical concept of 'fitness landscapes' (Kauffman, 1993; Kauffman et al., 2000), where peaks and troughs relate to areas of high and low fitness, respectively. O'Brien and Bentley (2011) see the example of spark arrestors on the smokestacks of the US locomotives in the nineteenth century in these terms. More than 1000 patents were taken out to solve the problem of trains causing fires while keeping the draft as unobstructed as possible. In this case there was no entirely successful solution, and this new adaptive space remained a rugged fitness landscape with a number of more or less equally fit local optima or peaks.

Previously empty or newly created niches offer new possibilities for innovation, either because there is no previous history from which to learn or because existing solutions may not work in the new niche. On Kaufmann's adaptive radiation model, whether biological or technological, there is an initial stage in which there are long jumps to new places in the fitness landscape, a second stage when the broad landscape has been explored and local 'hill climbing' occurs, because earlier choices constrain subsequent options in a process of so-called 'generative entrenchment' (Wimsatt, 1986), and a third stage of relatively little change where adaptations to local peaks cannot be improved but selection between different peaks begins to occur. Lake and Venti (2009) followed through the work of Van Nierop et al. (1997) and showed that the evolution of the bicycle did indeed follow this model.

When technologies involve complex and difficult production processes then they are far less likely to be reinvented if lost, simply because of that difficulty. Moreover, Roux (2010) makes the point that training in any production process that involves the acquisition of high levels of expertise that take a long time to acquire is likely to restrict innovation, because the whole process of learning is designed to ensure high-fidelity transmission, to fix particular sets of skills and knowledge (cf Martin, 2000); this may be particularly the case with physical expertise and motor skills. Only the most expert, those who have complete control of all aspects of a process and its associated knowledge, are likely to transcend the limits of what they have learned and invent something new. Roux cites (2010: 224) the example of inventions in the field of pyrotechnology by traditional craftsmen in India, which were only made by those who were most skillful, individuals 'exceptional as much for their skills as for their rarity'.

But Roux makes a further and more specific point relevant to the evolutionary trajectories of the more complex technologies, not least copper and iron production, that have emerged in the last 7000–8000 years. If the transmission of technologies based on novel principles involves a long apprenticeship that excludes the possibility of becoming correspondingly adept at other skills then it will almost inevitably result in a closed and more or less fragile technological system, at least to start with, because the effective population size of those involved in the activity in these circumstances will be very small. First, it will only be possible for relatively small numbers of individuals to undertake the apprenticeship. Second, not all societies will be able to sustain the required division of labor. Third, for various reasons, including people's desire to protect their livelihood, they are likely to keep their knowledge and expertise secret and either transmit it vertically to offspring or charge a significant entry fee. In these circumstances it may only take localized historical events, such as the destruction of local elites that supported specialists, to put an end to a technology altogether even if it was a functionally effective one, as Roux shows in the case of wheel-turned pottery in the ancient Near East.

A Case Study from Early Technology

How such processes work in the case of iron production has recently been examined by Charlton et al. (2010), who have taken an evolutionary approach to understanding preindustrial bloomery iron-smelting technology in a case study from north west Wales. Despite the technical complications of addressing this subject, it has the advantage that the problem can be clearly framed. There is no doubt about the goal (at least in general terms) and the conditions required to successfully smelt iron are well understood, arising as they do from universal properties of the materials involved. The bloomery method involves "the solid state reduction of iron oxides into a spongy mass of iron, called a bloom, and the production of a ferrosilicate slag" (Charlton et al., 2010: 353), based on the combination of iron ore and charcoal in a furnace supplied with air, where temperatures can reach up to 1400 °C, which is still below the melting point of iron. It was invented and diffused in several parts of the world and it seems safe to say that its spread and effective use did not involve any causal knowledge of the chemistry involved (cf Mokyr, 2000). Indeed, insofar as people formulated causal principles they were almost certainly completely mistaken.

Following the procedure above for the study of a technological lineage, the first issue is to identify patterns of cultural descent in the methods used and to distinguish variation arising from transmission from that relating, for example, to the local ore or fuel type; and then to characterize the forces affecting that variation, in a situation where, by the very nature of the process, there are only a limited number of successful solutions. The most informative source of information on the

processes involved in past episodes of early iron production is chemical variation in the slags produced as a waste product. In this case then the data are quantitative variations in the chemistry of chronologically ordered slag deposits and the problem is: can we establish whether or not there is a signal of cultural descent in the chemical variation? And if so, what can we infer about the factors affecting the transmission processes that produced it?

Charlton (2009) showed convincingly that a transmission signal could be identified in the slag chemistry, distinct from the effects of ore and fuel composition. In terms of the forces acting on the technical knowledge and practices passed on from one iron producer to another, it is easy to imagine that there might be some more or less random variation in exactly what was done each time. It is also likely that there would be strong selection for those practices that were successful, though, given the complexity of the process and its many stages, it would not necessarily be easy to identify precisely what produced a successful smelt on any given occasion. From the viewpoint of the smelters it is thus likely that transmission would be affected by results bias, albeit in a very noisy form, based on characteristics that they could observe and the connections they were able to make between variation in those characteristics and their techniques of ore preparation, furnace operation, etc. From the viewpoint of the smelting recipes as opposed to the smelters, incidentally, it could be argued that it represents a process of selection, since recipes would be differentially reproduced depending on their ability to successfully smelt iron. The results of Charlton et al. (2010) suggested that initially all changes related to furnace operation could be accounted for by a drift process but that at a certain point a second effective procedure was more or less accidentally discovered and a decision was taken to make use of the two distinct procedures, visible in consistently different slag signatures, one of lower yield than the other but producing a higher quality product in the form of steel. At the same time there were clear trends in the use of manganese-rich ores with better fluxing capabilities, and evidence of decreased variability in reducing conditions related to results bias: that is to say the iron makers consistently reproduced the airflow conditions that gave the best results for a given recipe.

However, this was a very small operation, using only a single furnace, and at present we do not know if the discovery of these Welsh iron smelters was also independently made by others, or if it was passed on outside this group. Roux's points regarding the closed and fragile nature of transmission networks in the context of preindustrial craft specialization would lead us to hypothesize that innovations made by this group of smelters could easily have been lost. It goes without saying that in this case we have no idea how these changes in the iron-production lineage impacted the survival and reproductive success of the smelters themselves since we have no evidence on this matter.

The subtle ways in which selection operated in the context of early complex technologies, often leading to optimal solutions, is also illustrated by Jackson and Smedley's work on medieval glass production in northern Europe (2008). Here bracken was used as a main source of plant ash for glass production. Jackson's analysis of the chemical composition of bracken ashes showed that it changes over the course of the growing season, with the concentration of SiO_2, CaO, Fe_2O_3, and MnO increasing throughout the season and K_2O and P_2O_5 peaking in mid-June and then declining. This makes mid-June the best time to harvest bracken since the alkali concentrations necessary to produce glass are high, and other components that produce less satisfactory outcomes, like coloring, are still low. The appreciation that this was the case, obviously without any knowledge of the relevant chemistry, was encapsulated in the recommendation to be found in contemporary documents about glass making that for the best results bracken should be harvested by the feast of St John the Baptist, 24th June.

Such examples show that we can realize the potential of cultural evolutionary theory for going beyond the tautology that superior technologies spread because they are superior. We can test hypotheses about the forces acting in any particular case. In this we are aided by the fact that there are independent engineering criteria for a technology's relative effectiveness, which can be established by experiments if they are not already known (cf Boyd et al., 2013); experiments can also help us to investigate the costs as well as the benefits by means of optimality studies. Time invested in producing complex technologies is time that could potentially be spent in other useful activities; they have an 'opportunity cost'. Bettinger et al. (2006) provide a productive model of technological intensification that addresses these cost–benefit issues and shows how they illuminate the use of different foraging technologies in prehistoric California. Of course, material costs are also relevant. An interesting example of where increasing costs have changed the direction of selection back to a simpler technology is the resurgence of animal traction for agriculture in parts of Africa as the costs of fuel and machinery have increased relative to local incomes (see www.atnesa.org).

The Cumulative Evolution of Technology

For cumulative evolution to occur, there needs to be some sort of balance between innovation and the rate of loss of existing technological attributes, determined at least partly by transmission fidelity. Obviously, if innovations are not retained then there is no possibility of accumulation and the same is true if fidelity is so high that innovations never occur. A simulation of a simple cultural transmission model by Lewis and Laland (in press) showed that the most significant factor affecting the build up of cumulative culture was cultural loss, and that a major difference was made by minor improvements in the fidelity of transmission, which led to increased longevity of cultural traits, while forms of innovation involving the combination of existing traits also played a significant role, much more so than the appearance of complete novelties.

In the case of genetic variation it is basically the case that mutations are random, though, of course, different genes have different mutation rates. In the case of cultural inventions it seems clear that rates of innovation in specific areas have varied over time. One tendency has been to take the 'necessity is the mother of invention' view of these, in which, when people are in a situation which they know is not sustainable, they are more likely to take risks and carry out trial-and-error experimentation (Fitzhugh, 2001). As Henrich (2010) points out, however, experimental evidence tends to be against this, and the risks involved are certainly very considerable, from devising

alternatives to embarking on them without prior knowledge of the costs and benefits. The contrasting view, not that they are mutually exclusive, is that they are more likely to arise simply as a result of the existence of larger effective populations, in terms of absolute size, degree of networking or both, since these are likely to increase the innovation rate per unit time and to increase the potential for the new combinations of existing elements that what Roux calls 'continuous inventions' generally represent. We have noted already that the collapse of populations and social systems leads to the loss of complex technological lineages that have only a few specialist bearers but it is now time to examine the issues involved in more detail.

The best-known evolutionary model that looks at the implications of specific innovation and transmission processes and their link to demography is that of Henrich (2004). This is based on a model of learning in which individuals attempt to imitate the most skilled individual available to them. Most individuals will fail to reach that level, so there will be a distance between the modal skill level in the population and the best. However, there will be a certain probability that an individual will exceed the current best and a new, higher, most skilled level will result. In these circumstances, given a constant gap between the best level and the modal level, the result will be an improvement in the modal level. The probability of improvement or decline in the population modal level depends on the ratio of the gap between the mode and the best, on the one hand, and the dispersion of the distribution of skill levels on the other. If the gap is small and the dispersion is large then improvement will be far more probable than in the opposite case. For a given ratio, though, Henrich shows that what happens will depend on population size, since improbable events will occur more often in larger populations. For very complex technologies where the gap between the modal level and the best is large and the variation between individuals is small, then a large population will be required to maintain or improve the technology. Thus, if external forces cause a decline in the population size the most complex technologies are likely to be lost. Simpler ones, even if they are lost, have a much higher probability of being reinvented. Henrich showed that this process could account for the well known and apparently deeply puzzling cultural impoverishment of the aboriginal Tasmanians after Tasmania was cut off from the Australian mainland at the end of the last Ice Age. More generally, "It is the selective transmission of lucky errors and occasional experiments that drives much of the evolution of adaptive technology, skills, beliefs, and practices" (Henrich, 2004: 202), and makes it strongly dependent on population size. Henrich's result has subsequently been confirmed by Kobayashi and Aoki (2012), who showed that a version of the model with the more satisfactory assumption of overlapping rather than discrete generations produced an even stronger population effect.

As we have seen already, the substantive assumption in Henrich's argument that real improvements are difficult to make because of the sheer amount of cultural knowledge embedded and embodied in human artifacts and cultural practices is supported by the ethnographic and archaeological work of Roux (2010), which also brings out the point that we always have to consider what is the relevant effective population size in any given case. In the example of Henrich's proposal for Tasmania the interacting population size decreases because of the loss of contact with mainland Australia.

As technologies get more complex, they include more elements. Lehmann and Wakano (2013) look at the effect of the multidimensionality of cultural traits on the process of cumulative evolution; in other words, where the best payoff depends on getting the right combination of a number of different features, for example, different aspects of size and shape of an artifact. With increasing numbers of dimensions there are far more ways of making things worse than making them better. Where the number of dimensions is very high then even a learner with very high computational ability going through different combinations and their effects in their imagination will not find the optimum, but a population of payoff-biased learners making uncorrelated errors will be able to reach it if it is sufficiently large. At least until the recent past effective population sizes may not have been large enough and for this reason it may be that many early technologies carried the equivalent of what in genetics is referred to as 'drift load', where deleterious mutations accumulate in the genome (cf Shennan, 2001). In other words, on this line of argument, cumulative technology does not necessarily result in improved performance. An excellent example of the kinds of complexity and multidimensionality involved is provided by Lombard and Haidle's (2012) construction of what they call the 'effective chain' of activities for the production of bows and arrows, based on evidence from Middle Stone Age Africa (see also Lemonnier, 1992 for other examples).

The general argument about the importance of population size for cultural complexity is supported by Kline and Boyd's (2010) study of marine fishing technology in Oceania. This showed a correlation between the number and complexity of marine fishing tools and the size and connectedness of island populations, with smaller and more isolated islands having fewer and less complex tools than larger and less isolated ones. Recently, experimental results have also demonstrated the cultural complexity – population size link (Derex et al., 2013; Muthukrishna et al., 2014).

These examples make the point that though the general human propensity for high-fidelity social learning (e.g., Dean et al., 2012; Haun and Over, 2013) is a prerequisite, specific instances of cumulative technological evolution are actually a property of specific populations or metapopulations linked by transmission processes. Selection will be operating on them through the cost–benefit dimension but, even in cases where the cost–benefit ratio is favorable, transmission failures, including the fact that early networks were often fragile, can overwhelm selection and lead to cultural loss, which is not necessarily reversed by reinvention.

Conclusion

The cultural evolution approach to technology is an extremely powerful one. Far from encouraging the tautologous view that what is prevalent is by definition what has been competitively successful, work in cultural evolution has demonstrated the complexity of making inferences about the forces at work while providing the tools to deal with it, including cost–benefit analyses and mathematical modeling. Moreover, the set of processes it

postulates, involving the generation of variation, its transmission, and the action of various sorting processes on what is transmitted provides a transparent basis for understanding how technology can be cumulative but also how cumulative evolution is specific to particular interacting 'effective' populations and therefore open to both devolution and optimality failures. Who you know is at least as important as what you know (cf Henrich, 2010). Early complex or specialist technologies had a number of intrinsic features that would have encouraged small effective population sizes, in terms of both absolute numbers of practitioners and the likelihood of them sharing information. Finally, the framework also makes clear what it is that is evolving – technological lineages – and thus directs us both to characterizing them and forcing us to think about the relations between them and populations of human agents.

Abstract

The 'social construction of technology' (SCOT) is one approach among several constructivist ways of studying science and technology that emerged in the 1980s. SCOT can be used to denote two different things. First, it is a research approach to study technical change in society, both in historical and in contemporaneous studies. And second, it is a theory about the relation between society and technology. This article sketches the genealogy of the social construction of technology by distinguishing mild and radical versions. Within the radical versions, broad and narrow forms are identified; the narrow one is denoted by the acronym 'SCOT.' Historically, the development of SCOT is closely linked to the sociology of scientific knowledge and to the science, technology, and society movement in the 1970s. An important starting point was to criticize technological determinism. In the 1980s and 1990s, it developed primarily as an academic enterprise, but then also found application in the policy domain, in innovation management, and in discussions about new forms of democracy.

Constructivist Studies of Science and Technology

The social construction of technology (SCOT) is one approach among several constructivist ways of studying science and technology that emerged in the 1980s. Here, 'constructivist' means a scholarly orientation that treats the truth of scientific facts and the working of technical artifacts as accomplishments – as being constructed – rather than as intrinsic properties of those facts and machines. The term 'social construction of technology' can be used to denote two different things. First, it refers to a research approach to study technical change in society, both in historical and in contemporaneous studies. Second, it signifies a theory about the development of technology. Historically, the development of SCOT is closely linked to the sociology of scientific knowledge (SSK) and to the science, technology, and society (STS – an acronym later used as much for science and technology studies) movement in the 1970s. In the 1980s and 1990s, it developed primarily as an academic enterprise, but then also found application in the policy domain, in innovation management, and in discussions about new forms of democracy.

The phrase 'social construction' was first used by Berger and Luckmann (1966) in their *Social Construction of Reality: A Treatise in the Sociology of Knowledge*. Building on the phenomenological tradition in philosophy and social theory, and particularly on the work of Alfred Schutz, they argue that social reality is constructed through human actions and that the processes through which it is constructed should be the object of the sociology of knowledge. Berger and Luckmann focus on the social construction of ordinary knowledge of the sort that we use to make our way in a particular society. They are concerned with the reality of social institutions and their focus is on society at large, rather than on natural reality and the subcultures, such as fields of science and technology, that contend with it. Nevertheless, provocative lines of scholarship developed around such themes as the social construction of mental illness, deviance, gender, law, and class. In the 1970s, the theme of social construction was applied to scientific facts (Latour and Woolgar, 1986[1979]), and in the 1980s developed for an approach to artifacts (Bijker et al., 2012 [1987]).

Constructivist studies of science and technology come in a wide variety of forms, both mild and radical (Sismondo, 1993). The mild versions merely stress the importance of including the social context when describing the development of science and technology. Examples in the history of technology include Constant's (1980) account of the turbojet revolution and Nye's (1998) studies of the electrification of America. The radical versions argue that the content of science and technology is socially constructed. In other words, the radical claim is that the truth of scientific statements and the technical working of machines are not derived from nature alone, but are constituted in social processes. Radical constructivist studies of science and technology share the same background and have similar aims, and to an extent studies in both areas have been carried out by the same authors. The remainder of this article will focus on technology studies and more precisely on the radical versions of SCOT.

The Origin and Development of the Social Construction of Technology

SCOT grew out of the combination of three distinct bodies of work: the STS movement, SSK, and the history of technology. The first started in the 1970s, mainly in the Netherlands, Scandinavia, the United Kingdom, and the United States. Often led by science and engineering faculty members, its goal was to enrich the curricula of both universities and secondary schools by studying issues such as scientists' social responsibilities, the risks of nuclear energy, the proliferation of nuclear arms, and environmental pollution. The movement was quite successful, especially in science and engineering schools and faculties, and some of the STS courses were incorporated into degree requirements.

SSK emerged in the late 1970s in the United Kingdom on the basis of work in the sociology of knowledge, the philosophy of science, and the sociology of science. The central

methodological tenets of the 'strong program' (especially its symmetry principle) seemed equally applicable to technology. The symmetry principle called for a similar explanatory approach to scientific knowledge, regardless of whether it was now held to be true or false; in other words, sociological interests and group processes would be used to explain the development and acceptance of 'true' as well as 'false' knowledge. In studying technology, this should mean that working and nonworking machines were to be analyzed symmetrically and in the same terms.

In the history of technology, especially in the United States, an increasing number of scholars began to raise more theoretical and sociologically inspired questions (Constant, 1980; Hughes, 1983; Cowan, 1983). Path-breaking advocacy for this body of work in the history of technology was provided by the reader edited by MacKenzie and Wajcman (1999[1985]). Citing the title of this volume, the phrase 'social shaping of technology' is often used to denote a broader area of research, including work in industrial sociology, technology policy, and the economics of technical change.

Researchers from these three traditions convened an international workshop in 1984 in the Netherlands. The subsequent volume – *Social Construction of Technological Systems* – from that workshop, edited by an STSer, a historian of technology, and a sociologist of scientific knowledge, has been heralded as the starting point of SCOT. On the occasion of the Massachusetts Institute of Technology (MIT)'s 150th anniversary, this volume was included in the list of 30 most influential titles ever published by MIT Press, and it was republished in an anniversary edition 25 years later, with a new preface reviewing the development of the field since 1987 (Bijker et al., 2012[1987]). To understand the role of this workshop and volume, it is helpful to distinguish between a broad and narrow usage of the phrase 'social construction of technology' (but do note that both notions fall within the radical meaning of social constructivism).

When broadly used, 'SCOT' encompasses all the work represented in the 1987 volume, including the actor–network approach by Callon, Latour, and Law, and the technological systems approach advocated by Hughes. The author uses the acronym SCOTS, after the title of the 1987 volume, to indicate this broad meaning. Used more narrowly, it refers primarily to the program set out by Pinch and Bijker (1984). For this latter program of the social construction of technology, the acronym SCOT was introduced; but this acronym is now increasingly used in the broad sense too, without reference to one specific approach in constructivist studies of technology. The remainder of this article is primarily about SCOT in the narrow sense, although in the last sections, the author broadens the review by returning to SCOTS.

SCOT developed like any normal scientific program: its agenda, central concepts, and even unit of analysis shifted in response to research findings and discussions among contributing scholars. In that sense, one can distinguish early and late (or recent) versions of SCOT. An important, although negative, starting point for SCOT was a criticism of technological determinism. Technological determinism was taken to comprise two basic claims: (1) technology develops autonomously and (2) technology determines societal development to an important degree. These claims were seen as intellectually impoverished and politically debilitating. Proponents of SCOT argued that technological determinism involves a poor research strategy, because it entails a teleological, linear, and one-dimensional view of technological development. In addition, they considered it politically debilitating because technological determinism suggests that the paths taken by technological development are inevitable, thus making social and political interventions a futile endeavor. To bolster this critique, it was necessary to show that the development, stabilization, and even working of technology are socially constructed, with the emphasis on social. Key concepts in this program, as will be discussed in the next section, are 'relevant social group,' 'interpretive flexibility,' 'closure,' and 'stabilization.' The unit of analysis was the single artifact (that is, a tool, a device, or a machine). The choice of the artifact as unit of analysis was a choice of the 'hardest possible case,' similar to the choice of mathematics and natural sciences by the Strong Programme (David Bloor) and the Empirical Programme of Relativism (Harry Collins). To show that even the working of a bicycle or a lamp is socially constructed seemed a harder task, and thus – when successful – more convincing, than to argue that technology at a higher level of complexity and aggregation was socially shaped.

The agenda of demonstrating the social construction of artifacts by detailed analysis at the microlevel resulted in a wealth of case studies. A few years later, the program was broadened in two ways (Bijker and Law, 1992). First, new questions were raised at a meso- and macrolevel of aggregation: for example, about the political construction of radioactive waste, clinical budgeting in the British National Health Service, or technically mediated social order. Second, the agenda was broadened to include, once again, the issue of technology's impact on society, which had been bracketed for the sake of refuting technological determinism. Concepts developed for this agenda were 'technological frame,' and various conceptualizations of the obduracy of technology. The unit of analysis was broadened from the singular technical artifact to the more comprehensive and heterogeneous sociotechnical ensemble. The emphasis now was on 'construction' rather than on 'social' – a similar shift had occurred in the social construction of science, for example, when Latour and Woolgar dropped the word 'social' from the subtitle of their book *Laboratory Life* when it was reprinted in 1986. The aim became to study the mutual shaping, or 'coproduction,' of society and technology, rather than explaining how distinct 'social factors' shaped a separate domain of 'technology' (Oudshoorn and Pinch, 2003). Current research in SCOT continues to broaden the empirical, theoretical, and, indeed, political agendas of SCOT. The author returns to these agendas in the final two sections.

The Social Construction of Technology as a Heuristic for Research

As a heuristic for studying technology in society, research in SCOT can be set out as a progression through three steps (Bijker, 1995).

Key concepts in the first step are 'relevant social group' and 'interpretive flexibility.' An artifact is described through the eyes

of relevant social groups: groups that are relevant because the way they attribute a meaning to the artifact, shapes the artifact's development. Accordingly, relevant social groups can be identified as actors who refer to the artifact in the same basic way. For example, bicycle producers, young athletic ordinary users, women cyclists, and anticyclists each described the high-wheeled ordinary bicycle in the 1870s in a distinctive way. Because the description of an artifact through the eyes of different relevant social groups produces different descriptions – and, in a sense, different artifacts – the researcher is able to demonstrate the 'interpretive flexibility' of the artifact. Although it is common to speak of one artifact, in practice there are many. In the case of the ordinary bicycle, for example, it was an unsafe machine in the eyes of women, but a macho machine in the eyes of the young male ordinary users. For the typical woman of the era, the bicycle was a machine in which the skirt got entangled and from which the woman frequently made a steep fall; for the 'young man of means and nerve' riding the bicycle was a means to impress people (including young ladies).

In the second step, the researcher follows how interpretive flexibility diminishes over time, as some artifacts gain dominance over others and meanings converge, and in the end one artifact results from this process of social construction. Here, key concepts are 'closure' and 'stabilization.' Both concepts are meant to describe the outcome of the process of social construction. 'Stabilization' stresses process: a process of social construction can take several years in which the degree of stabilization slowly increases up to the moment of closure. 'Closure,' a concept stemming from SSK and describing the way scientific controversies end (Collins, 1985), highlights the irreversible end point of a discordant process in which several artifacts (e.g., bicycle designs) coexisted for awhile, before being succeeded by a single model.

In the third step, the processes of stabilization described in the second step are analyzed and explained by interpreting them with a broader theoretical framework. The explanation seeks to answer why a given social construction process follows one course, rather than another. The central concept here is 'technological frame.' A technological frame structures the interactions among the members of a relevant social group, and shapes their thinking and acting. It is similar to Kuhn's concept of 'paradigm' with one important difference: 'technological frame' is a concept that applies to all kinds of relevant social groups, while Kuhn intended 'paradigm' exclusively for scientific communities. (However, these days, the popularized 'paradigm' seems to apply to all sorts of communities and imagined communities.) A technological frame is built up when interaction 'around' an artifact begins. In this way, existing practice guides future practice, although without logical determination. The cyclical movement thus becomes artifact, technological frame, relevant social group, new artifact, new technological frame, new relevant social group, etc.

Typically, a person will be included in more than one social group, and thus also in more than one technological frame. For example, the members of the Women's Advisory Committees on Housing in the Netherlands are included in the technological frame of male builders, architects, and municipality civil servants. This allows them to interact with these men in shaping public housing designs. But at the same time, many of these women are included in the feminist technological frame, which enables them to formulate radical alternatives to the standard Dutch family house that dominates the male builders' technological frame (Bijker and Bijsterveld, 2000).

This three-step research process thus amounts to (1) sociological analysis of an artifact to demonstrate its interpretive flexibility, (2) description of the artifact's social construction, and (3) explanation of this construction process in terms of the technological frames of relevant social groups. The remainder of this section discusses some methodological issues and points of criticism.

It is important to appreciate that SCOT provides a research heuristic for interpretive sociology, not a research machine to churn out case studies as Russell (1986) and Winner (1993) seem to suggest. For example, the adage 'identify all relevant social groups by searching citations of the artifact by a variety of actors' does not diminish the researcher's obligation to decide which groups are important to include in the account, and which groups only obfuscate the picture by adding useless details.

As a research heuristic, SCOT shows its debt to the history of technology by emphasizing case studies and narrative, and to SSK by a preference for qualitative methods such as ethnography. Besides providing a theory of technology and society (as discussed in the next section), SCOT aims at helping researchers to give detailed and insightful accounts of the development of technology in society. Concepts such as 'relevant social group' and 'interpretive flexibility' primarily help to open up a case and to ask original and thought-provoking questions; they are less important for telling the story (see the debate between Angus Buchanan, John Law, and Philip Scranton (1991)). These case studies may be historical or contemporaneous. When doing the latter kind of study, the researcher will often find herself or himself drawn into the case and become one of the actors.

It is also a mistake to think that SCOT research focuses only on the early stages of an artifact's development, the design and prototype phases. If the key idea of SCOT – that all kinds of relevant social groups contribute to the social construction process – is taken seriously, then one should also accept that this construction process takes place in all contexts and all phases. Thus, for example, the automobile in the United States acquired a specific functionality in rural areas where it was used as a stationary power supply to washing machines, butter churns, corn shellers, water pumps, and wood saws, well after it had come off the production line as a transportation vehicle (Kline and Pinch, 1996).

Two concepts, seamless web and symmetry, may be fruitfully used to highlight one specific methodological characteristic of SCOT research. The phrase 'seamless web of technology and society' is often used as a reminder that nontechnical factors are important for understanding the development of technology, and that these factors are closely related to one another as well as the technology. A second, more sophisticated, meaning is that it is never clear a priori and independent of context whether an issue should be treated as technical or social. Was the Challenger accident a technical failure, an organizational mistake, or primarily a lack of adequate funding (Vaughan, 1996)? The activities of engineers and designers are best described as heterogeneous engineering, network building,

or system building, rather than as straightforward technical invention. The recognition that all kinds of social groups are relevant for the construction of technology supports this second way of using the seamless web metaphor. The third interpretation of that metaphor extends the symmetry principle from the strong program in the sociology of knowledge into the principle of general symmetry. Not only should one treat working and nonworking machines symmetrically, but also the very distinction between the social and the technical world can be treated in that way. The 'stuff' of the fluorescent lamp's invention is economics and politics as much as electricity and fluorescence (Bijker, 1995). Let us call this 'stuff' sociotechnology. The relations that play a role in the development of the fluorescent lamp are thus neither purely social nor purely technical; they are sociotechnical. The principle of general symmetry casts this into a methodological principle: human and nonhuman actors should be treated similarly, and the construction of society and the construction of technology should be explained in symmetrical terms (Callon, 1986). In other words, technical reductionism and social reductionism are both out of play as explanatory strategies. Instead, new forms of explanation need to be developed. The next section includes an example.

The Social Construction of Technology as a Theory of Technology in Society

SCOT also provides a theoretical perspective on the relation between technology and society, and on their joint developments or coevolution. As discussed earlier, the development of technology can be explained as a social process in which an open variety of relevant social groups participate. This social process does not stop when an artifact leaves the factory, but continues when users endow the technology with specific uses and meanings. Laws of physics and economics are relevant but insufficient to characterize a technology's development. Artifacts can be shown to have interpretive flexibility, due to the different constructions that various social groups make. When these relevant social groups interact, typically one meaning of the artifact will gain dominance and stabilize. At the end of that social process, closure occurs, and interpretive flexibility vanishes.

Analogously, the development of social institutions in modern society cannot be fully understood without taking into account the role of technology. Such institutions as the church, capitalism, the government, organized labor, communication systems, and education may keep the social fabric of society together; but where would all of these be without technology? Social order in modern society can only be explained by reference to technology (Latour, 1992). This requires a view of technology's impact on society. In SCOT, conceptualizing the hardness or obduracy of technology does this.

An artifact can be hard in two distinctly different ways. The first form, 'closed-in hardness,' occurs when the humans involved have a high inclusion in the associated technological frame. For example, upon meeting problems with printing a letter, a student with a high inclusion in the personal computer (PC) users' technological frame will check cabling, control panels, and printer definitions. Only after some time will it occur to her that she could also write the letter by hand: she was 'closed in' by the PC technology. Another student having the same problem, but with a low inclusion in the PC users' technological frame, has no clue about cables or control panels; he can barely locate the power switch. He experiences the second kind of impact by technology: 'closing-out obduracy.' He sees no alternative but to leave the technology aside and pick up his fountain pen. In both cases, the technology has an impact on these students, but in completely different ways.

These two forms of hardness of technology can also be seen on the societal level. Automobile technology, for example, exerts a 'closed-in hardness' on the inhabitants of Los Angeles, much differentiation within auto culture, but few alternatives outside it. The standardization of main power voltage and wall plugs means a 'closing-out obduracy' to most people; accept it by buying the right plug and apparatus, or refrain from using electricity.

This constructivist analysis provides a theoretical perspective on both SCOT and the technological impact on society. It offers a reconciliation of the previously opposed social constructivist and technological determinist views. This reconciliation needs some theoretical elaboration to extend the conclusion of the previous section: that the distinction between technology and society can be transcended and that the proper subject matter for analysis is sociotechnology. The concept 'technological frame' provides the theoretical linkage between the two views.

A technological frame describes the actions and interactions of actors, explaining how they socially construct a technology. But since a technological frame is built up around an artifact and thus incorporates the characteristics of that technology, it also explains the influence of the technical on the social. Part of the societal impact of the standard Dutch family house was that it dominated architectural thinking in the 1950s through the 1970s, and thus made it very difficult to conceive alternatives; architects and even members of the critical Women's Advisory Committees were 'closed in' by the builders' technological frame, only seeing the two-parent–two-child house.

Since the early 1990s, researchers in social constructivist studies of technology had indeed recognized that explaining the social shaping of technology could only mean half an understanding of the relations between technology and society (Bijker and Law, 1992). Technological determinism, as Wyatt (2008) convincingly argues, needs to be taken seriously. Research into the hardness of technology thus adds to a more balanced understanding of the relationship between the technical and the social; Hommels (2005) explicitly builds on SCOT and actor–network theory in her analysis of the relations between technology and society, while Leonardi (2012) also brings in organizational sociology to understand how the intertwinement (or 'imbrication' as he calls it) of technological and organizational changes results in new forms of sociomaterial stability. Work on the embeddedness of technology in society, partly in the context of policy-oriented European projects, or on the 'domestication' of technology further explores this agenda of an integrated understanding of SCOT and the technical impact on society (Lie and Sorensen, 1996). The earlier work of Don Ihde (1979) and postphenomenology approaches in the philosophy of

technology similarly give a new interpretation of the role of the material artifacts (Verbeek, 2005).

Broadening the Social Construction of Technology

To understand the recent developments in SCOT, it is helpful to widen our scope beyond the initial narrow interpretation of SCOT. In their new preface, Bijker and Pinch review the developments in SCOT at large, or SCOTS, since 1987 (Bijker et al., 2012[1987]).

One development is the investigation of a whole new range of empirical domains, with associated conceptual innovations. Internet and computer studies are the first example (Abbate, 1999; Edwards, 1996). In nanotechnologies, there is a broad recognition among scientists, engineers, and policy makers of the need to look beyond the laboratory (Bijker et al., 2009; Mody, 2011). Scholars such as MacKenzie (2006), Callon (1998), and Pinch and Swedberg (2008) now also extend SCOT, broadly conceived, into the study of economics and financial markets. The newly emerging field of sound studies is heavily indebted to SCOT too (Pinch and Bijsterveld, 2012).

Within organizational sociology, there has been a recent interest in SCOT by scholars such as Garud and Karnoe (2001), and Orlikowski (1992). These studies have a clear interventionist agenda and help to translate SCOT insights to a wider readership of managers and organization specialists.

A Turn to Politics and the Normative

We live in technological cultures; our modern, highly developed societies cannot be fully understood without taking into account the role of science and technology. SCOT and the broader SCOTS program both offer a conceptual framework for politicizing this technological culture. Although such a technological culture already is infused with politics, 'politicizing' here means showing hidden political dimensions, placing issues on the political agenda, and opening issues up for political debate. The SCOT approach not only gives an affirmative answer to Winner's (1980) question 'Do artifacts have politics?' but it also offers a way to analyze such politics. Technology is socially (and politically) constructed; society (including politics) is technically built, and technological culture consists of sociotechnical ensembles.

Studies that develop this agenda, again, typically draw on social constructivist technology studies in the broader sense. One of the most fruitful bodies of work is the analysis of gender and technology (Lerman et al., 2003). Works such as MacKenzie's (1990) history of guided missiles, Hecht's (2009 [1998]) history of nuclear power in France, Gottweis' (1998) study of genetic politics, and Vaughan's (1996) account of the Challenger disaster demonstrate that the new framework can also be productive for the analysis of classical political themes.

The issue of political decision making about technological projects acquires special guise in the light of social constructivism. If it is accepted that a variety of relevant social groups are involved in the social construction of technologies, and that the construction process continues through all phases of an artifact's life cycle, it makes sense to expand the set of groups involved in political deliberation about technological choices. Thus, several countries have experimented with consensus conferences, public debates, and citizens' juries. One of the key issues here is the role of expertise in public debates. The SCOT approach suggests that all relevant social groups have some form of expertise, but that no one group – for example, scientists or engineers – has a special and a priori superiority over the others.

A final development with a strong political and normative edge can be mentioned, which is the turn toward development and globalization. Work in SCOT has increasingly turned to a more global arena, rather than restricting attention to the northern and western hemispheres. This leads, for example, to a fresh approach to long-standing questions in other domains, compared with the typical SCOTS perspective, on the relations between science, technology, and society. One example is cold war history in connection to issues of development and colonization (Hecht, 2011), another is the role of innovation in public health (Engel and Bijker, 2012). In addition to investigating new topics at a global scale, studies are reconceiving traditional technology as a site for sociotechnical innovation (Mamidipudi et al., 2012). Possibly even more exciting than applying the received SCOTS perspectives to new geographies and questions, is the promise of truly new insights by extending the research into these domains, raising new questions, and developing collaborations with scholars and practitioners from Asia, Africa, and Latin America. Such new insights will, the author expects, range from the empirical to the theoretical, and from the epistemological to the political.

Technology Transfer

Shiv Visvanathan, Centre for the Study of Developing Societies, Delhi, India

This article is reproduced from the previous edition, volume 23, pp. 15532–15537, © 2001, Elsevier Ltd.

Abstract

Following a discussion of some basic concepts and paradigms in science and technology studies, the article traces how debates on technology transfer have resonated with wider debates on development. Technology transfer has produced a spate of critical discourses centering on intermediate technology, alternative technology, and alternative science. The transfer of military technology is also considered, suggesting proliferation is 'officially impermissible diffusion.' The article then examines the impacts and risks of development, the difficult questions raised by biotechnology, and the 'holy grail' of information technology. The author sees the concept of transfer of technology as one of the great myths of the twentieth century: the belief that the natural diffusion of science and technology can fulfill any democratic dream.

The concept of technology transfer (hereafter, transfer of technology or TOT) has diverse roots: in myth, in the nineteenth century preoccupation with the diffusion of technological artifacts, and in the economics of knowledge. The Promethean act of stealing fire from the gods could be considered a creation myth of technology transfer. Lynn White's classic essay on the origin and diffusion of the stirrup is paradigmatic of the studies on the diffusion of technological artifacts (1962). But TOT as an everyday concept could only come into being with the idea of what Whitehead dubbed the 'invention of invention.' In *Science and the Modern World*, he observed, 'to understand the modern epoch, we can neglect railways, telegraph, radios, spinning machines, and synthetic dyes. We must concentrate on the method itself' (1938: p. 118). Whitehead insisted that 'scientific knowledge is not an abundant storehouse from which one readily helped oneself. An intense period of imaginative design lies between them. One element in the new method is how to go about bridging the gap between a scientific idea and its ultimate product' (1938: p. 18).

The idea of the TOT reflects at once a model of governance, a civics we may say, and a paradigm for the interaction between science and technology (S&T). Also present in this concept is a recognition that science and technology operated as parallel streams throughout most of history. If anything connected them, it was the use of scientific instruments. Till the nineteenth century, science was not a systematic part of the productive process. Economic historians now agree that science played little role in the industrial revolution, which was more the work of craftsman inventors who had little systematic education in science or technology. The concept of technology transfer recognizes the problematic relation between S&T and seeks to increase the reciprocity and frequency of the interaction.

In its most rudimentary form, the TOT concept is founded on the idea of the innovation chain as a sequence of the three stages, namely invention, innovation, and diffusion, which are non-monotonic. Invention represents the conceptualization of a scientific idea conventionally in a laboratory and its concretization in a sample or prototype. Innovation represents the scaling up of the product or process for commercialization, and diffusion is the wider extension of the product in society. Innovation chains represent the lifecycle of a scientific idea within the technological and commercial domain. The nature of the schema disguises certain ideological and cultural biases. First, it assumes that science and technology axiomatically have separate spheres of operation, which the creativity and purity of science requires. Institutionally, science was seen as operative in laboratories and universities; technology in factories and engineering studios. The innovation chain was a linear sequence proceeding from pure science to applied science to development and production. TOT was conceived as following the same linear pathway.

Second, the schema is associated with a set of conceptual separations that tended to reinforce a ritual and institutional separation among the three stages. The relation between pure science, applied science, and development provided the stuff of science policy in the USA for years. If one seminal book embodied this model, it was Vannevar Bush's *Science, The Last Frontier*, which provided the paradigmatic formulation for the science policy of the Cold War years (1945). Bush's work was representative of the time and reflected the era's static understanding of the categories of research. Bush argued that basic research is the engine of technological progress and that it must be separated from applied research because applied research invariably drives out the pure.

Third, present in Bush's writings was not only an understanding of the dynamics of science but of nation building. Bush argued that nations which depend on others for their pure science would lose their competitive edge in world trade. The TOT model thus embodied the ideological assumptions of a particular subculture of science which equated invention with basic science and superiority in basic science with supremacy in world politics (see Stokes, 1997). This subculture was challenged both by the Japanese successes in competing with America in the 1980s and by a newly revisionist history which saw S&T as a more interactive field, in which scientists like Maxwell, Pasteur, and others derived their pure science questions from industrial and agricultural problems. The linearity was also challenged by the development of the new materials sciences which posited and institutionalized a reciprocal relation between science and technology (see Roy, 1970). But there were also ideological reasons for the collapse of the

conventional paradigm. If the quarrel of the categories constituted the stuff of the science policy discourse in the Anglo Saxon postwar world, the challenges to technology transfer models came from a different array of positions in the Third World.

Critical Discourses

The debates on technology transfer resonated with the wider debates on development. As development produced discursive epicycles of equal development, community development, participative development and sustainable development, technology transfer too produced a spate of critical discourses centering on intermediate technology, alternative technology, and alternative science. These responses were not merely driven by academic critiques but evolved as philosophies of grassroot movements.

Present in all these approaches was a geography of power. The innocent horizontality of TOT was now read across the center-periphery axis. The political economy of technology transfer saw the basic choices of S&T as emerging from the metropolis. The periphery was regarded not as a source of independent innovation but only as a recipient of it. The idea of TOT was embedded in the policy of import substitution; industrialization was seen as a passive civics that pulled its subjects into forms of governance over which they did not have active control.

The recognition of intellectual and economic inequality underlying TOT produced spectrum of responses. From Latin America came the work of the center-periphery theorists who argued through LAFTA and UNCTAD for better terms of trade. Here technology was absorbed in the wider discourse of political economy. Inspired by his work in Burma, E.F. Schumacher articulated the idea of intermediate technology (1973). The Vietnam War, the energy crisis and the peace movement produced a search for soft energy paths captured in the idea of appropriate or alternative technology (see Lovins and Price, 1975). All these critiques continued to see science as universal knowledge but felt that technology was local and adaptable. They believed that local knowledges, ethno sciences, could be brought into play to produce a more local and creative technology less discordant with culture. A fourth approach, however, sought to challenge the epistemological hegemony of science, seeking an alternative basis for science through critiques of Judeo-Christian cosmology and the ethnocentrism of modern science. The Indian chemist C.V. Seshadri argued that if the notions of efficiency implicit in the laws of thermodynamics were applied to Third World societies operating at ambient temperatures, such decisions would work against tribals in the Third World, or peasants opting for indigenous or traditional agricultural practices (Seshadri, 1993). The idea of intermediate technology and the emphasis on local knowledges was gradually adopted in World Bank models of technology transfer. The epistemic critique however faced a more ambiguous fate and was subjected to benign neglect.

All the above critiques tried to modify TOT as an antiseptic managerially limited discourse and to relocate it within the wider politics of knowledge and production. They reworked technology within an ethical worldview, arguing that the TOT was also a transfer of values (see George, 1984: pp. 75–76). Ivan Illich's work on education, medicine, and energy was a critique of the basic professionalism implicit in the TOT model (1992). He saw it as a disabling, iatrogenic program, a cultural code for disempowerment.

The effervescence of these critical movements dimmed by the 1990s, though they continue to inspire the struggle against large dams, the critique of forestry, and the logic of urban planning in Third World countries. Intermediate technology in its heyday produced a flowering of locally sensitive technologies such as biogas and modified kitchen stoves, and also revived traditional technologies for housing (see Warren et al., 1995). As dissenting imaginations, they were powerful, but their critical edge was blunted or absorbed by the UN sponsored idea of sustainable development. Sustainable development gave the TOT model a new lease on life by offering the possibility of a balance between ecology and development, renewability and productivity, the long run and the short run.

By the 1970 and 1980s, Science and Technology Studies (STS) had advanced beyond marginality to produce a more variegated set of discourses. The resurgence of the economics of scientific knowledge revitalized studies of the R&D system. Till the 1960s, economists thought that knowledge, like waste, was something external to the production system. Knowledge was not treated as a factor of production like land, labor, or capital. The work of Jewkes et al. (1958), Rosenberg (1976), Freeman (1974), and Machlup (1962) had a far-reaching impact in visualizing technology transfer as a policy discipline. They provided systematic studies exploring the relation between R&D expenditure and rates of productivity. They emphasized the systematic role of patents in evaluating the productivity of such systems and introduced methodologies of cost-benefit analysis to audit TOT processes. In all, they provided a fine-grained set of analytical constructs and empirical studies that helped professionalize science policy as a discipline. They also emphasized that the rationality of the firm was altered by the military-industrial complex.

Transfer of Military Technology

The conceptual world of technology transfer still operated at a split-level with a tendency to dichotomize civilian and military transfers of knowledge. One link between the two was the concept of 'spin-off,' the idea that investments in military research eventually had civilian potential and therefore legitimized the former. The other was the idea of conversion which suggested the transformation of swords into ploughshares, a notion which became popular after the Cold War. One of the finest critiques of military innovation chains was Mary Kaldor's *Baroque Arsenal* (1982). Kaldor argued that while military technology was once innovative, it had become decadent or baroque after World War II. She traced the baroquization of military technology to the interaction between 'the capitalist dynamic of arms manufacturers and the conservatism that characterizes armed forces and defense departments in peace time' (Kaldor, 1982: p. 4). Baroquization is a consequence of the paradoxical dynamic between, on the one hand, armies which cling to designs from the previous war and, on the other, the competition to stay in

business and win contracts that demands incessant technological effort.

The consequence is an involuted technology of perpetual improvements within a conservative framework. What we face is a narrowing of options, greater uniformity, and diminishing returns. More and more money is expended on small improvements ultimately to obtain military hardware which is difficult to maintain. Cost factors increase to such an extent that by 2020, Kaldor suggests, the defense department might be able to afford one plane. Built into such technology as well is planned obsolescence. What was created by Alfred Sloan of General Motors for the car becomes a part of weapons systems. The useful life of a weapon is much shorter than its physical life because of the inexorable power of obsolescence. The emphasis is more on luxuries, accessories, and minor improvements.

Kaldor warned that such military technology when transferred is dangerous both for industrialized and industrializing countries. She argued that the idea of 'Atlanticism' is not just a set of treaties, but a shared technological paradigm posited on a bipolar confrontation between Western and the (then) Eastern totalitarian systems (see Kaldor, 1987: p. 143). She showed how the security concerns of the UK, France, and Germany make them replicate the baroque technologies of the USA, resulting in similar cost overruns and duplication. Worse, alternative forms of defense, including Precision Guided Munitions (PGM) which implied decentralized and dispersed military organizations, could not be developed.

The impact of arms transfers is predictable in developing countries, as illustrated for instance in the regime of the Shah of Iran. The high incidence of arms transfers impairs the capacity to import what is needed for development and industrialization. Once a weapon system has been imported, a chain of supplementary imports is induced. Modern fighter aircraft, tanks, and naval units require an extensive network of support facilities including spare parts and presence of foreign experts. 'The installation of sophisticated military infrastructure is also suboptimal for the development process and often negative for existing traditional infrastructures. Simply put the stability of triage or a road for a tank has to be much higher than for a bullock cart' (Locke and Wulf, 1984: p. 114). The chain of demands appears endless. This pervasive logic of military technology independently suggests that Third World nations can arrive at a self-reliant position in military technology only if they abstain from imitating the military paradigms – both doctrines and weapons systems – developed in the context of the confrontation between industrialized nations. In this context, the Vietnam War was a model confrontation between two modes of technology transfer. Unfortunately the debate did not sustain itself into the new millennium.

Technology transfer as a discourse made incremental responses to new problems. It responded gradually to issues of obsolescence, pollution, proliferation, risk, spin-off on separate grids, while also keeping civilian and military processes on separate registers. There was a need to link concepts such as obsolescence and proliferation. If obsolescence raised problems of value and time in TOT models, proliferation emphasized the question of excess. Military technology represents the classic case, but all too often military technology transfer is restricted to a limited scenario with the legitimate nation-state as actor, without realizing that the smuggler, the mercenary, and eventually even 'rogue states' may be the agents of proliferation or illegitimate transfer.

Proliferation is officially impermissible diffusion. It is a cancerous threat to the ordered chaos of diffusion. As good civics, diffusion reinforces the system of innovation. Nuclear proliferation, however, threatens it, demanding a network of laws, treaties, alliances to restrict its flow. One is simultaneously caught in the debate between atoms for peace and atoms for war, unless one agreed with Robert Jungk (1976) that the distinction was a spurious one, difficult to maintain empirically. The question of proliferation was handled at two levels – technologically as well as legally and politically. Technological measures attempted to control latent proliferation through interventions in the nuclear fuel cycle. Scientists have proposed that proliferation resistance become a design criterion for nuclear energy systems through such techniques as isotopic denaturing. There was, however, a realization that such technical measures needed to be complemented with the political. Within the political domain, proliferation was met by two general strategies. First was the universalist argument in which, through the Nuclear Non-Proliferation Treaty and other legal measures, a full framework of integrated treaties worked for the elimination of nuclear regimes. The other, more restricted effort seeks to argue that a *controlled* spread of nuclear energy alters the behavior of adopting states, adding a dose of restraint and confidence to their behavior.

TOT and the Risks of Development

Throughout the 1960s to the 1980s, the TOT discourse operated between the axes of disarmament and development. It took four decades of development for experts to realize that development, the chief objective of TOT, might produce more refugees than war. India by some counts has over 40 million refugees from development projects; in fact it arguably has more refugees from development than from the wars it has fought after independence. Not unnaturally, some grassroots groups considered TOT as a continuation of war by other means (see for instance, Visvanathan, 1997: p. 41).

The accidents at Windscale, Chernobyl, and Bhopal introduced into the public sphere of TOT discourse the concept of risk and the more comprehensive idea of the risk society (Beck, 1992). The 1984 gas leak at Bhopal, India, the world's biggest industrial disaster, proved that international transfers of technology needed to be located within a wider ethics of responsibility than mere compensation. One needed not only a more systematic right to information and disclosure but also ideas of justice and rehabilitation beyond monetary compensation. The issues of pollution and the proliferation of hazardous waste facilities introduced into the TOT domain new and enlightened legal ideas, including the polluter pays principle. Actors within the legal system realized that as technology moves from certainty to uncertainty, and even to risk, one has to redefine both the rationality of technology and the notion of responsibility. With the rise of environmentalism, risk assessment became a significant element of the TOT discourse. It also

brought to the forefront the latent public aversion to science, as enacted in citizens protests. One had to ask whether citizens' worries about environmental hazards from carcinogenic pesticides, nuclear wastes, loss of global ozone was grounded, and then to develop methodologies for resolving such controversy. The work of Douglas and Wildavsky (1982), Brian Wynne (1987), Kristin Shrader-Frechette (1991) were all attempts in that direction, but with different sensitivities to the requirements of science and the demands of democracy.

The question of risk also prompted inquiry into the rationality behind technology. Ulrich Beck (1992) went so far as to institutionalize the problem. Beck argued that in advanced industrial society the social production of wealth is accompanied by the social production of risks. He claimed one needed a new concept of a risk society with which one not only acknowledged that modernization produces risks, but one also systematically and openly sought to answer how risks could be 'prevented, minimized, dramatized and extended' (Beck, 1992: p. 21). The notion of the risk society led to a range of debates in the social sciences, raising interesting questions about the role of experts in technology transfer, the question of trust in science, and the construction of scientific knowledge itself.

Meanwhile a revisionist history of the Green Revolution was altering the perception of one of the paradigmatic successes of the technology transfer discourse. The Green Revolution, a project which involved the transfer of hybrid, fertilizer-sensitive seeds to India, Pakistan, and other developing countries, was originally seen as a benign example of successful TOT which saved these countries from starvation and made India self-sufficient in food. Norman Borlaug, one of pioneers of the Green Revolution, received the Nobel Prize for peace. Robert Anderson challenged the received wisdom of the Green Revolution by arguing that it involved not merely high yielding packages of seed, pesticides and fertilizer but also incorporated social ideas of changing agricultural society. 'The broad economic links between modernized agricultural production and US economic interests were crucial elements in the strategy from the beginning' (Anderson et al., 1991: p. 361). Francesca Bray, arguing from a different perspective, showed that Green Revolution concentrated on only a few crops, 'wheat, and rice for human consumption, corn and soybean for animal feed and cotton for industry' (Bray, 1994: p. 30). The capital-intensive, highly mechanized model hastened soil erosion and environmental degradation. Bray and later Vandana Shiva (1992) particularly attacked the monocultural mindset behind such TOT, which ignored the productivity and sustainability of polycultural systems, which not only used several varieties of crop but had several uses for various parts of the crop. Such crops were also resistant to pests. It was the impoverishment of gestalts that constitutes the most devastating aspect of the critique of the Green Revolution as TOT.

TOT and Biotechnology

But narratives change and so do battle sites. By 1990, even its pioneers recognized the Green Revolution as a dated narrative. The productivity levels of wheat and rice had leveled off and the scene shifted to biotechnology as the site for the second Green Revolution. While critiques of the Green Revolution came after the event, the movements against biotechnology were spawned almost simultaneously.

The question of the transfer of biotechnology raises fundamental questions for the innovation process in the Third World countries. Pat Mooney (1983, 1998) documents how many crops developed by farmers over centuries became the property of a multinational at the stroke of a pen. Patenting, which was seen as a legal frame for recognizing original innovation, became a technique for appropriating the legacy of innovation in agricultural societies. Important controversies in the 1990s centered around *neem* and *basmati* rice. The growing opposition to chemical products led to a search for natural pesticides and to the *neem*. By 1985, US and Japanese firms had taken out a dozen patents on *neem* pesticides and *neem* toothpaste. The question one has to ask is whether *neem* patents constitute novel forms of knowledge or are such forms of novelty only based on the ignorance of a 2000-year-old tradition of biopesticides in India?

The controversy over *basmati* rice raised similar issues. In 1997, a patent was granted to Ricetech, Inc., a US company, on *basmati* lines and grains. The *basmati* variety was derived from the Indian *basmati* and crossed with semi-dwarf varieties. The question is whether Ricetech *basmati* is the Indian *basmati* and novel at the same time. If *basmati* patents were recognized in India, Indian farmers would ironically be forced to pay royalties to Ricetech.

A patent does not recognize the prior custody of farmers over their seeds. There is no recognition of prior art. Culturally, the patent defines agriculture as an activity performed in a laboratory rather than on a farm. It is a derecognition of an entire intellectual commons. The juridical framework of GATT and TRIPS has possibilities of becoming a new enclosure movement – comparable in spirit to the actions of fifteenth century British landowners – which turns a farmer who saves and replants the seed of patented or protected plant into a violator of the law.

There was a second, equally fundamental problem. Hybridization disables the seed from reproducing itself and forces the farmer to return to the breeder for further stock. Farmers who were custodians of the seed now were systematically deskilled both by technology and law. Finally, there is the ethical question of whether life forms can be patented at all as many of these communities locate the seed within the domain of the commons and the gift.

TOT and Information Technology

If biotechnology appears as a dismal science for the TOT process, information technology, as a narrative, was more celebratory. The rise of technologically innovative groups in Silicon Valley, California, created a new paradigm for industrialism outstripping in its impact Boston's legendary Route 128 (Castells, 1996). Silicon Valley created a false belief that distance and location did not matter in the TOT. Over the last decade, governments in India, China, Malaysia have pursued the holy grail of reinventing Silicon Valleys in their countries. Information technology and the legend of the innovative successes of Bill Gates and Sabir Bhatia, of Oracle, Sun Microsystems, and Intel created a myth that innovation

chains could reproduce themselves anywhere. As Manuel Castells remarked:

> The development of the information technology revolution contributed to the formation of the milieux of innovation where discoveries and applications would interact, and be tested, in a recurrent process of trial and error, of learning by doing; these milieus required (and still do in the 1990s, in spite of on-line networking) spatial concentrations of research centers, higher education institutions, advanced technology companies, a network of ancillary supplies of goods and services, and business networks of venture capital to finance start-ups.
>
> (Castells quoted in McGray, 1999: p. 153)

Information Technology is symptomatic of the cornucopian myths present in TOT. At its most reductive level, technology transfer is a methodology of hope combining the powers of science and technology. It appears as a discourse on management but, as it unravels, its reaches beyond management to the complexities of law, political economy, ethics and anthropology. What begins as a science policy issue transforms itself into a multidisciplinary exercise. Technology transfer is one of the great myths of the twentieth century, a belief that science and technology, if naturally diffused, can fulfill any democratic dream. It is the task of science and technology studies to show the lags, the gaps, the ironies that sustain the myth. What one needs to chronicle is these very lags, gaps, worries and possibilities as the myth of TOT acts itself out in the form of policy.

Teens, Gender, and Self-Presentation in Social Media

Susan C Herring, Indiana University Bloomington, Bloomington, IN, USA

Abstract

This article is concerned with how teenage boys and girls present themselves through online social media such as Facebook, Twitter, blogs, and chat forums. Based on research conducted mostly in the United States, it describes and considers the implications of social media use, profile construction, visual and textual self-presentation, profile visibility, truthfulness, and other facets of teens' self-presentation in relation to their gender.

Introduction

Teenagers – young people between the ages of 13 and 19 years – have been identified as the generation with the highest Internet use since the late 1990s (Kraut et al., 1998). As 'digital natives' (Prensky, 2001) who were born and raised in the age of computers and online communication, today's teens share self-created content, post their opinions, and link to other content online more than any other demographic group (Lenhart et al., 2010). The often-heralded democratizing potential of the Internet (e.g., Ess, 1996) has been realized especially strikingly for youth: at no other time in history have young people enjoyed such opportunity to make themselves visible to, and heard by, diverse audiences. At the same time, this exposure entails risks. Moreover, there are gender differences in teens' Internet use, as will be discussed below. Unless otherwise specified, the claims in this article pertain to English-speaking young people in the United States, about whom the bulk of research on online behavior has been conducted.

This article is concerned with how adolescent boys and girls present themselves to others through online social media. Social media are Web-based (and increasingly, mobile) services that allow users to connect and interact with friends, acquaintances, and strangers. Examples include social network sites such as Facebook and Twitter, media-sharing sites such as YouTube and Flickr, blogs, and other Web-based communication forums. Social media "build on the ideological and technological foundations of Web 2.0, and … allow the creation and exchange of User Generated Content" (Kaplan and Haenlein, 2010: p. 61).

Much of that content is photographs, links, and textual information that social media users post to present an online self. Self-presentation is generally considered to be motivated by a desire to make a favorable impression on others, or an impression that corresponds to one's ideals. As such, self-presentation is centrally involved in impression management and the projection of an online identity (cf Schlenker, 1980). Research has shown that teens' online self-presentations differ in various ways, projecting gendered identities.

The term gender is used here to refer to the socially constructed roles that individuals adopt and present to others. Gender normatively maps onto biological sex, and we use the terms *boys* and *girls* to refer to the normative mappings, albeit with the caveats that (1) it is often difficult to determine an Internet user's actual biological sex or offline gender and (2) gender and sex exist along a continuum, and intermediate realizations of both are possible. The following sections describe teenagers' social media use, profile construction, visual and textual self-presentation, profile visibility, truthfulness, and other facets of self-presentation in social media sites in relation to normative gender. The article concludes by discussing the implications of these findings and the future outlook they suggest.

Social Media Use

Teens as a demographic group are avid Internet and social media users in the United States. A recent survey found that almost all U.S. teens (95%) aged 12 through 17 years are online, compared to only 78% of adults. Of these teens, 80% have profiles on social media sites, as compared to only 64% of the online population aged 30 years and older (Lenhart et al., 2011). According to a study conducted by the Kaiser Family Foundation, individuals of 11–18 years of age spend on average over 1.5 h per day using a computer and 27 min per day visiting social network sites, more than one-fourth of their daily computer use (Rideout et al., 2010).

At the same time, because of their inexperience, limited capacity for self-regulation, and susceptibility to peer pressure, teens may not fully understand the possible repercussions of Internet use and are at some risk as they navigate and experiment with social media (O'Keeffe and Clarke-Pearson, 2011). Concerns have been expressed about the amount of time teens spend online (cf Gross, 2004), (lack of) parental control over teenage Internet use (Wang et al., 2005), privacy, risky behaviors such as sexting, cyberbullying, 'Facebook depression,' and exposure to inappropriate content (O'Keeffe and Clarke-Pearson, 2011). Yet other scholars have critiqued the tendency for the mass media and some scholars to fuel 'moral panics' regarding youth online (boyd, 2007; Herring, 2007), pointing out that the incidence of harm to teens resulting from Internet use is actually very low. Moreover, a survey conducted by Wang et al. (2005) suggests that parental awareness of and involvement with their children's Internet use are increasing, compared with earlier decades when Internet-illiterate adults often had little idea what their tech-savvy offspring were doing online. Finally, even given the risks, teens derive many benefits and gratifications from Internet use.

 http://dx.doi.org/10.1016/B978-0-08-097086-8.64108-9

Gender differences, as well as some similarities, are apparent in social media site preferences and amount of use. The sites most popular with teenagers and young adults of both genders (as of 2014) are Facebook and Twitter, which constitute social network sites according to the three criteria articulated by boyd and Ellison (2007): they have user profiles, allow for 'friending' (or 'following' on Twitter), and contain social networks that can be navigated to encounter friends of friends. A Pew study conducted in the United States found that 80% of online teens use social network sites, Facebook being the most popular, with 93% of those teens reporting its use (Lenhart et al., 2011). Teens have been leaving Facebook recently, however, and migrating to newer social media platforms such as Instagram, Snapchat, and WhatsApp, which they consider 'cooler' and where they are less likely to encounter their parents (Kiss, 2013). Girls on average spend more time on social network sites and use them more actively than boys do (Brenner, 2012; Rideout et al., 2010). More girls than boys use Facebook and Twitter; female users, including teens, also predominate on the online pinboard Pinterest. Conversely, more males use music-sharing sites such as last.fm, as well as Reddit, a social news Web site known for its sometimes misogynistic content (HuffPost Women, 2012; Williams, 2012). The gender breakdown for Instagram and Snapchat users, the majority of whom are teens, was roughly equal as of October 2013 (Duggan, 2013).

Gender differences are also present in the ways teens use the Internet and social media, although usage patterns have shifted over time. In 1999, teenage boys in the United Kingdom reported using computers more often than girls and feeling more comfortable doing so (Livingstone and Bovill, 1999). By 2004, however, both genders were embracing the Internet as a means of communicating with their friends: Gross (2004) found that the most common activity among American middle and high school students was chatting via instant messaging. In 2007, teenage girls in the United States were more active bloggers than boys – perhaps the first time that females were more active participants than males in a public mode of computer-mediated communication (CMC). Boys, meanwhile, were more likely to upload online videos and use video-sharing applications (Lenhart et al., 2007). In recent years, boys still spend more time using computers, especially playing video games and visiting video Web sites such as YouTube (Rideout et al., 2010). However, girls create and share more video (Lenhart, 2012) and also are more likely to video chat, in keeping with their more active texting and mobile communication behaviors (Lenhart et al., 2010). Regardless of gender, most teens in the United States today spend part of their leisure time online visiting social media sites (Rideout et al., 2010).

The main reason young adults in the United States give for visiting social network sites is to connect and communicate with others and to satisfy their curiosity about their online friends and acquaintances (Urista et al., 2009). Adolescent girls generally use them to communicate with peers and to reinforce preexisting relationships, while boys more often use the platforms to meet new people and make new friends. Boys are also more likely to identify with groups on social network sites that differ from their offline peer circles (Barker, 2009; Lenhart and Madden, 2007a).

A consequence of gender differences in social media use is that girls and boys frequent somewhat different sites and engage in different, albeit overlapping, activities on the sites they visit. However, most social media contexts involve a mix of both genders. This has implications for how teens self-present.

Social Media Profiles

Profile Content

Self-presentation online takes place primarily through social media profiles. Many social media sites allow users to create a profile and visually display connections to their social network (boyd and Ellison, 2007). In addition, many sites allow users to upload and share personal information, pictures, links, music, and other multimedia with their friends' or followers' networks. Profiles first attracted widespread attention on social network sites such as Friendster and MySpace in the middle of the last decade, and they have since been incorporated into many other social media platforms, including chat sites (Kapidzic and Herring, 2011), Wikipedia (Lam et al., 2011), and the mobile photo-sharing application Instagram (Ngak, 2012).

Profiles represent a change in the way Internet users self-present. In earlier textual interactive environments such as chat rooms and MOOs (Multiuser Dimensions, Object Oriented), it was not uncommon for users to invent nicknames and imagined personae (Bechar-Israeli, 1995; Nakamura, 1995). Now, popular platforms such as Facebook explicitly encourage users to provide truthful personal information. Thus teens tend to present their 'real identity' on these sites through their usernames, photographs, and other information that they provide about themselves (Zhao et al., 2008). Although this limits users' ability to experiment with their identity online – for example, it is more difficult to pretend to be a different gender, as was possible in text-based anonymous spaces (Danet, 1998) – young adults can still manipulate their profiles to create impressions that they consider favorable through various means, including number of friends (Ellison et al., 2007), lists of interests (Liu, 2007), and pictures that display particular tastes and preferences (Salimkhan et al., 2010).

Teenage girls and boys differ to some extent in the types of content they post to their profiles. In a study of profiles on several social networking sites, including Facebook, female participants from the United States reported that they post 'cute' pictures, while male participants were more likely to share pictures and comments that they described as self-promoting and that contained sexual content or references to alcohol (Peluchette and Karl, 2008). On a teenage dating site, however, teen girls' self-descriptions contained significantly more references to sex than boys' did (Pujazon-Zazik et al., 2012). Girls in both the United States and Sweden are more likely to display friendship ties on social media, for example, by posting photographs of themselves with their friends (Lenhart and Madden, 2007b; Sveningsson Elm, 2007). Boys, meanwhile, are more likely to orient toward technology, sports, and humor in the information they post to their profile (Sveningsson Elm, 2007) and to share their location and/or phone number (Lenhart and Madden, 2007b; Pujazon-Zazik

et al., 2012). In an earlier analysis of English-language teenage blogs, Huffaker and Calvert (2005) also found that boys provided more information about their location. Moreover, gay boys more often shared their sexual orientation, although there was no difference in how much personal information girls and boys shared in their blogs overall or in their mentions of romantic relationships, both of which were plentiful. Similarly, both boys and girls on a popular Swedish social networking site strongly emphasized their romantic relationships (Sveningsson Elm, 2007).

In a study conducted in the United States of young adults' perceptions of what constitutes appropriate content on social network sites, Peluchette and Karl (2008) found that the research participants expressed little concern about sharing updates and pictures on social network sites such as Facebook. Female participants expressed more concern about future employers seeing some of their pictures and comments, especially those related to alcohol, than males did; however, overall, young adults appear to utilize social media primarily as a way to attract and form relationships with peers, and they are unconcerned with maintaining a professional image (Peluchette and Karl, 2008). This practice can create problems for young adults when they go on the job market. A 2013 survey found that 1 out of 10 young job applicants were rejected because of the content they had posted on social media, including 'provocative or inappropriate photos or posts,' and 'content about drinking or using drugs' (Sherman, 2013).

Visual Self-Presentation

Visual content is a central resource for creating an online impression (Ellison et al., 2006). While in earlier environments such as chat rooms, girls and boys could represent themselves only through the use of textual descriptors (e.g., Nakamura, 1995) or cartoon avatars (e.g., Scheidt, 2004), recent platforms tend to promote the use of photographs in online profiles. Teens and young adults pay special attention to the photographs they select for their profiles (Salimkhan et al., 2010).

Teenagers' main criterion for choosing profile photographs is a belief that they look good in them. According to a study conducted in the United States among young adults, both genders perceive that girls place more emphasis than boys on selecting pictures in which they are attractive (Manago et al., 2008). Manago et al. (2008) interviewed young adults in focus groups about their self-presentation strategies on the social networking site MySpace and found that participants of both genders reported presenting stereotypically gendered images, e.g., of attractive women and strong men. In a survey of Estonian teenage social media users (Siibak, 2009), girls more than boys self-reported selecting pictures in which they thought they looked attractive. Similarly, in a study of teen chat sites, Kapidzic and Herring (2011) found that the vast majority of girls posted profile photographs that presented them in a seductive manner (looking up or sideways at the viewer) and suggestive dress (showing cleavage). Photo choices among male teens were more varied, including dominant, idealized, and affiliative behaviors in addition to seductive behaviors, although there was a tendency for boys to choose photos that showed them at a farther distance from the camera and looking away from the viewer. However, there were also some boys who posed seductively, for example in photos that showed them shirtless. Some young males in Manago et al.'s (2008) study also reported trying to look sexually attractive, a growing trend in social media, especially among Caucasian males in the United States (Kapidzic and Herring, 2014).

On the one hand, these behaviors reproduce cultural gender stereotypes and media portrayals of the sexually available woman and the strong, emotionally distant man (Kapidzic and Herring, 2011; Siibak, 2010). In particular, they reflect the prevalence of pornography dominated by masculine fantasy on the Internet: Studies show that nearly half of American teens surveyed have viewed sexually explicit Web sites, and those who have tend to have less progressive gender role attitudes, as well as more permissive sexual norms (Brown and L'Engle, 2009).

On the other hand, the trend in the early twenty-first century for both boys and girls to self-sexualize in their visual online presentations suggests a more general phenomenon of 'self-commodification' (Siibak, 2010). Most of the time, this is probably unconscious as a result of internalization of media images (Donnelly, 2011). In a study of 288 Facebook users in the United States, Kapidzic (2011) found that young adults who internalized media messages about stereotypical looks were more likely to select profile photos in which they were posing seductively and revealingly dressed. The study participants displayed relatively high levels of media internalization overall, with females scoring significantly higher on the scale. Self-commodification may also be intentional, as in the case of a teenage boy who operated a pornographic Web site featuring images of himself for several years (Leary, 2007). Other cases are less clear: Are 12-year-old-girls who post 'slutty' pictures of themselves on Facebook (Williams, 2012; see also Ringrose, 2011) intending to advertise themselves as sexually available, or are they just imitating the media and their peers? Explicitly pornographic images are prohibited on most social media sites; however, what constitutes 'pornographic' is not always clear.

Profile Visibility and Perceived Audience

Online self-presentation raises privacy issues. Accordingly, most social media sites allow users to adjust settings to control who has access to view their profiles. There is evidence that girls limit the visibility of their profiles more than boys do. Patchin and Hinduja (2010) conducted a content analysis of 2423 teenagers' profiles on a popular social media site to determine to what extent adolescents share information publicly; they found that girls were 1.5 times more likely than boys to restrict access to their profiles. Similar findings were reported by Thelwall (2008a) in an analysis of the profiles of young adults on MySpace, as well as in a recent Pew survey, in which 21% of profile-owning boys in the United States reported leaving their profiles fully visible to the public, as compared to only 12% of girls. Three-fourths of the girls who were interviewed restricted their profile visibility to their friends only, whereas only half of the boys reported doing so (Lenhart et al., 2011). Girls may be especially concerned with assuring the privacy of their online profiles because of the greater tendency for females to be harassed online based on their gender. Results from the Growing

Up With Media Survey, a national survey of more than 1500 American teens aged 10–15 years, indicate that girls are significantly more likely to have experienced sexual solicitation (e.g., requests to talk about sex) and harassment in the form of mean comments on social network sites than boys (Ybarra and Mitchell, 2008). Girls' greater concerns about privacy and identity disclosure on social media sites may predispose them to interact with individuals they already know and trust (Muscanell and Guadagno, 2012).

Privacy settings give one a measure of control over one's audience. However, many social media users do not understand how to adjust the settings, or they ignore them. Before social network sites existed, moreover, privacy settings were uncommon, and access to many social media, such as chat and blogs, was effectively open to the Internet-using public. Despite this reality, teen bloggers, for example, often imagined their audience to be limited: other teens – their friends and romantic interests – but not usually their parents, teachers, or employers (cf Qian and Scott, 2007; Viégas, 2005). This misperception still seems to affect some teen social network users, who reveal compromising information (e.g., about alcohol consumption) and display themselves provocatively attired in their profiles even when the profiles are public. Alternatively, it may be that teen Internet users today are not very concerned with privacy (Kiss, 2013; Peluchette and Karl, 2008).

Another, perhaps related, way in which audience influences self-presentation is the fact that many social media environments popular with young people are heterosexual (by default) marketplaces where flirting and sexual come-ons are common activities (Herring and Zelenkauskaite, 2009; Kapidzic and Herring, 2011). It seems reasonable to suppose that much of teens' online self-presentation in these social media has as a subtext attracting potential partners, be it for sex, dating, online chat, or just to get attention.

Truthfulness of Self-Presentation

For all that it may appear to be self-revealing, the information that girls and boys display about themselves in their profiles is not necessarily accurate. Both genders report experimenting with their online presentation and posting untruthful information to their profiles, such as lying about their age to make themselves older. Results from a Pew survey indicate that 56% of American adolescents with online profiles have posted false information on social media sites. Teenage boys posted fabricated information more often than girls (Lenhart and Madden, 2007b). Moreover, in a survey of more than 300 Dutch adolescents, Valkenburg et al. (2005) found gender differences in the kinds of information male and female teens misrepresented in online interactions. Boys pretended to be more macho, whereas girls pretended they were older and tried to give the impression of being more beautiful. Another study by the Girl Scouts of America found that girls who would describe themselves as 'smart' or 'kind' offline were more likely to post they were 'fun,' 'funny,' or 'social' on social network sites, and girls with low self-esteem were somewhat more likely than girls with high self-esteem to describe themselves as 'sexy' and 'crazy' (Carmon, 2010).

Other research points to a tendency for both adolescent girls' and boys' online self-presentations to mirror their real self in terms of personality traits. Back et al. (2010) asked 236 young adults from Germany and the United States to describe their ideal self and answer a questionnaire to assess personality traits such as openness and extroversion; in addition, research observers rated the participants' profiles. The authors found that the participants' personality scores reflected the observer ratings better than the idealized self-descriptions. Thus while teens may consciously distort the truth to appear more attractive, they have less control over how their personality subconsciously influences their profile descriptions.

Textual Communication and Interaction

Teens also give off textual cues consciously and unconsciously in their online self-presentation (cf Goffman, 1959). This occurs both in descriptions in profiles and, more generally, in textual interactions with other people through chat, instant messaging, discussion forums, blog comments, and the like. Social media sites are increasingly incorporating such CMC features into their platforms.

Numerous studies from English-speaking countries have analyzed textual CMC and have identified gender patterns on the discourse-pragmatic and stylistic levels of language use. Guiller and Durndell (2007), for example, analyzed young adults' language use in computer-mediated discussion groups in Scotland and found that although male and female users did not differ in how they employed linguistic variables such as first-person pronouns, interjections, and imperative verbs, significant gender differences were evident in the use of many stylistic variables: males were more likely to use authoritative language and to respond negatively in interactions, while females were more likely to agree explicitly, support others, and make more personal and emotional contributions. These findings are consistent with observations reported earlier for adult English-language CMC by Herring (1993) and others. Similarly, in an analysis of interactions on five teenage chat sites, most of them based in the United States, Kapidzic and Herring (2011) found significant gender differences. On the pragmatic level, boys used manipulative speech acts more than girls did, inviting and directing others, whereas girls produced more reactive acts. At the stylistic level, boys' messages were more aggressive and flirtatious than girls' messages, which were most often friendly. In an analysis of positive and negative message tone on English-language MySpace profiles, Thelwall et al. (2010) also found that female messages had a positive tone significantly more often than male messages. Kapidzic and Herring (2011) concluded that gendered patterns of communication online have not changed appreciably in the last 20 years.

Findings at the structural level of language are not as distinct. In an analysis of instant messaging communication between young American adults, Baron (2004) found that females employed uncontracted forms (more formal) twice as often as males; females also used emoticons (less formal) more frequently. In Huffaker and Calvert's (2005) analysis of teenagers' blogs, boys used flirty emoticons significantly more often than girls did, although there was no gender difference in amount of emoticon use. Furthermore, Huffaker and Calvert found that while the adolescent boys in their sample used words that were active and resolute more often than the girls

did, there was no difference in the use of cooperative words, which they expected to find more of in girls' blogs. These mixed results seem to support the conclusion that gender differences are most pronounced at broader, stylistic levels of language use.

Sexualized language is prevalent in teenagers' online interactions with their peers. Subrahmanyam et al. (2006) explored the use of adolescents' linguistic choices related to describing sexuality in an English-language teen chat environment. Male teens communicated more explicitly about sex, whereas female teens used more implicitly sexual language, choosing sexualized nicknames and writing about sexual themes. Smahel and Subrahmanyam (2007) studied the process of partner selection in the same chat environment, analyzing the linguistic means by which users invited others to chat. The authors found that in both monitored and unmonitored chat rooms, 16% of all partner requests were invitations of an implicitly or explicitly sexual nature, and these were produced in equal amounts by boys and girls. Girls produced somewhat more partner requests, however. Relatedly, Pujazon-Zazik et al. (2012) coded content on 752 publicly available profiles on an English-language teenage dating site for mentions of risky behavior, such as content related to drugs, violence, alcohol, cigarettes, or sex in the teenagers' self-descriptions. Almost one-third of the descriptions (28%) contained reference to risky behavior, and 16% of those references were related to sex. Girls were more likely to include sexual references in their descriptions, while boys mentioned drugs more often.

Few studies have yet examined gender and language use on social network sites. An exception is Thelwall (2008b), who analyzed gender in relation to the use of swearwords on the profile pages of close to 40 000 MySpace users in the United States and the United Kingdom. Automated language analysis of the pages of users who indicated their age revealed that 16- to 19-year-old boys in the United States used swearwords significantly more than girls of the same age in their self-presentations; in the United Kingdom, however, there were no significant gender differences. Thelwall suggested that the fact that girls in the United Kingdom are incorporating traditionally male language such as strong swearing into their linguistic choices is reflective of deeper changes in gender roles in British society, as evidenced, for example, by the increasing acceptance of binge drinking by U.K. females.

Conclusion

While some similarities exist in social media use by teenage girls and boys, online presentations differ in various respects. The studies described in this article indicate that girls often choose to limit the visibility of their profiles by restricting access by people they are not connected to, whereas boys often allow their profiles to be viewed publicly. Moreover, boys more often post false information on their online profiles. Male and female teens also differ in their textual self-presentation: Boys' linguistic choices reflect assertiveness in both style and tone, while girls seem to aim to please boys and facilitate social interaction. Similarly, in their visual presentations girls most often choose pictures that indicate a desire to appear attractive and sexually appealing, while for boys the patterns are less clear. Both genders' choices of pictures for self-presentation can be seen to reflect sexualized media portrayals.

While such findings might not be surprising for adults, some authors have suggested that teenagers growing up with the Internet and at ease with the many platforms that facilitate interaction might move beyond stereotypically gendered behaviors in online communication (e.g., Huffaker and Calvert, 2005). Nevertheless, much of the recent research conducted on adolescents' online self-presentation points to the persistence of traditional gender stereotypes, both in the use of language and in the selection of images for display. The sexualization of boys diverges from the traditional pattern but is consistent with an overall trend toward what Ringrose (2011) calls the 'pornification' of online self-presentation.

Taken cumulatively, the research described in this article reveals the importance that adolescents place on displaying gendered identities in social media. This finding is not surprising since, in the teenage years, identity and sexuality start to play major roles in the lives of young people as they seek to define and explore who they are (Erikson, 1968). Social media sites and the profiles they contain provide young adults with a reference point in the process of developing their social identity. There they interact with their peers, the most important reference group for teens. boyd (2007) posits that "by looking at others' profiles, teens get a sense of what types of presentations are socially appropriate; others' profiles provide critical cues about what to present on their own profile" (p. 10). This observation helps explain the high degree of normativity within gendered self-presentations in social media.

Minority gender identities – of gay and transgender teens, for example – are also expressed through social media, although, what research exists on the subject suggests that popular sites such as Facebook, MySpace, and Twitter are heteronormative environments (e.g., Carstensen, 2009). Moreover, the one-to-many nature of such sites presents challenges for identity negotiation and information control for queer teens who are not 'out' to all the members of their network, leading some to adopt strategies such as coded reference to their sexuality or maintaining two Facebook accounts, one in which they are closeted and another in which they are out (Cooper and Dzara, 2010; Young, 2012). At the same time, social network sites provide questioning teens an opportunity to explore and reconfigure their gender identities, and in the process, to clarify to themselves who they are (Cooper and Dzara, 2010).

More generally, social media sites provide a space where teens can explore the effects of their self-presented image on others (cf Schlenker, 1980). In many cases, posting pictures and comments will generate positive feedback and could have a positive impact on teenagers' self-esteem. Less-desirable reactions to online self-presentation include negative commenting, cyberbullying, and harassment (Li, 2006), which can have serious psychosocial consequences. Moreover, comparing one's own appearance with that of others in social media can lead to feelings of inadequacy and depression (O'Keeffe and Clarke-Pearson, 2011).

Implications and Future Outlook

The research described in this article has implications for the safety and well-being of teenagers, and thus should be of

interest to parents, educators, and Internet policy makers as well as scholars. It also has implications for the development of sex and gender roles in adolescence and how these are affected by exposure to online content. To the extent that sexualized images, including pornography, affect sexual attitudes and behavior, psychologists as well as health care professionals have a stake in understanding teens' online self-presentations. Finally, the research contributes to a growing body of scholarship on the effects of computer mediation on human social behavior, suggesting, among other things, that profiles constitute invitations to social interaction in much the same way as offline self-presentations do, and that they can be manipulated in equally subtle ways – even, and perhaps especially, in social media environments that encourage truthfulness (Kapidzic and Herring, 2014).

As today's young 'digital natives' grow into tomorrow's adults, we might predict that their practices will increasingly enter the mainstream, from the use of social media to conduct all kinds of business to a lesser concern with privacy to more open attitudes toward sex. Based on reports that young people in the United States today are more tolerant of diversity than their parents' generation (Jones, 2013), we might also predict that more nontraditional gender identities will be openly expressed online. At the same time, it is to be expected that with age, inexperienced youth will understand better the possible undesirable consequences of their online self-portrayals, for example, as regards employment, and make less of their personal information available to mass audiences.

Abstract

The telegraph was an application of research in electricity and electromagnetism between 1800 and 1840. The first telegraph lines opened in Britain in 1837 and the USA in 1844. The telegraph remained the mainstay of rapid long-distance communication until practical long-distance telephony after 1900. After 1920, as long-distance telephone rates dropped, telegraphy's share of the long-distance communications market declined. By 1970 the overland telegraph industry in the industrialized world was dying. Submarine telegraphy survived longer; it remained the preferred medium for overseas communication until the installation of undersea telephone cables in the 1950s. After 1980 other technologies, such as facsimile and electronic mail, took over the role of long-distance record communications formerly supplied by the telegraph.

The telegraph was the outgrowth and application of advances in electrical science between about 1800 and 1840, particularly the discovery of galvanic electricity by Luigi Galvani and the invention of the electrical battery by Allesandro Volta around 1800, and research into electromagnetism by Hans Christian Oersted, Andre Marie Ampere, Joseph Henry, and Michael Faraday during the 1820s and 1830s. The first two telegraph lines were opened in Great Britain in 1837 and the USA in 1844. The telegraph was the only form of electrical communication until the invention of the telephone in 1876, and it remained the mainstay of rapid long-distance communication until the development of practical long-distance telephony after 1900. After 1920, as long-distance telephone rates dropped and many countries introduced airmail service, telegraphy's share of the long-distance communications market entered a long decline. By 1970 the overland telegraph industry in the industrialized world was dead or dying. Submarine telegraphy survived longer; it was the only medium for rapid overseas communications until the advent of transatlantic radiotelephony in 1927, and it remained the cheapest and preferred medium until the installation of undersea telephone cables in the 1950s. After 1980 other technologies, such as facsimile and electronic mail, took over the role of long-distance record communications formerly supplied by the telegraph.

In technological and scientific terms, the telegraph was important for three major reasons. First, telegraphy was the first major application of discoveries in electrical science, and it was one of the first technologies with a firm scientific foundation. Second, telegraph electricians during the mid-nineteenth century helped to establish the discipline of electrical engineering. Finally, technical problems, especially in submarine telegraphy, stimulated major scientific advances in physics and oceanography.

Telegraphy was the first technology to sever the connection between communication and transportation. Because of the telegraph's ability to transmit information almost instantly, it affected many aspects of society, culture, politics, international relations, and economics after 1840. It helped to create integrated national and international markets, sped the dissemination of news, provided a model for new literary forms, aided Western imperialism, and spurred national governments to develop telecommunications and technology policies.

The Telegraph in Great Britain

In the mid-1830s William Fothergill Cooke developed a telegraph which indicated letters by using the transmitted electrical current to deflect magnetized needles at the receiver. During the same period, Charles Wheatstone conducted several important experiments on the long-distance transmission of electricity. In February 1837, the two men pooled their efforts and in June they obtained a patent for an electromagnetic telegraph using five wires to deflect five needles in order to indicate letters of the alphabet. They built their first commercial line in 1838 and 1839. In late 1842, Cooke patented an improved telegraph which used two wires and needles, instead of five, to indicate letters; this halved construction and installation costs.

During the early 1840s, railways were the major customers of the telegraph. In 1846 Cooke and a group of investors founded the Electric Telegraph Company to build a commercial telegraph system for the use of the press and businessmen. By 1855 its network encompassed nearly every important town in England and Ireland. For the next quarter century, the Electric company dominated the industry but competed with four other companies for business. During this time the industry shifted from the Cooke and Wheatstone two-needle instruments to various forms of printing or recording telegraphs.

By the mid-1860s, much of the British public, Parliament, and the civil service supported the nationalization of the telegraph industry, claiming that Post Office operation would reduce rates, expand the network, and provide better service. In 1868, Parliament authorized the purchase of the telegraph lines, and the Post Office began operating them in February 1870. Despite initial successes, it was soon apparent that the British postal telegraph faced serious financial obstacles, including an inflated purchase price, unremunerative press and railway rates, commercial rates which barely broke even, and competition from the privately owned telephone industry.

At the turn of the century, telegraph traffic peaked at some 90 million messages. Throughout the following decades, traffic dropped and losses mounted because of competition from the

telephone and the letter post which delivered letters within the British Isles within 24 hours of posting. The telegraph's heyday was over by 1920, and by 1970 the telegraph had ceased to be an important communications medium in Britain.

The Telegraph in the USA

In 1837 and 1838, Samuel F.B. Morse publicly demonstrated his electromagnetic recording telegraph to prominent scientists and government officials. Morse's system at this time comprised an alphabetic code of dots and dashes, a telegraph key to encode messages, and a receiving register which recorded signals on to a moving strip of paper. Morse believed that the federal government should own and operate his telegraph, and hoped to convince the American government to purchase his system. In 1843, Congress gave Morse $30 000 to build an experimental line between Washington and Baltimore. This line began operation in May 1844, but the government refused to fund an extension of the line northward to New York. In 1846, the government turned over the Washington–Baltimore line to private investors.

Over the next 15 years, the telegraph network spread rapidly; by 1850, lines reached every important point east of the Mississippi River, and by 1861, a transcontinental line reached California. The major change to telegraph equipment in this period was the elimination of the recording register; operators shifted to sound reception by deciphering the clicks of the receiving magnet. During the late 1840s and early 1850s, a confusing welter of several dozen companies sprang up to build telegraph lines, many of them poorly organized and short-lived. During the late 1850s, a cartel of six companies coalesced and provided stability to the industry. The end of the Civil War in 1865 sparked a final wave of consolidation, and Western Union emerged in 1866 as the country's telegraph monopoly.

During the remainder of the nineteenth century telegraph technology remained relatively static. The only major advance arose in the 1870s, Thomas Edison's invention of the quadruplex which allowed the simultaneous transmission of four messages on a single wire. Between 1866 and 1910, Western Union faced two major challenges to its dominant position in the American communications market. During this period, a vocal and vigorous movement arose to nationalize the telegraph and place it under postal administration, and Western Union officials spent much time and energy defending their private monopoly to the public and to Congress. The telephone, independently invented in 1876 by Alexander Graham Bell and Elisha Gray, was Western Union's second major challenge. Bell offered to sell Western Union his patent, but Western Union refused and established a competing telephone system in the late 1870s using Gray's and Edison's patents. Because of Bell's superior patent position, Western Union withdrew from the telephone market in 1879 in exchange for Bell's promise not to compete with Western Union's long-distance telegraph business. In the 1870s and 1880s, the telephone could not operate over distances longer than a few dozen miles. However, by about 1890 telephone engineers expanded the range of audible conversations to a few hundred miles, culminating in the establishment of Bell's transcontinental telephone service in 1915. As Bell's long-distance network expanded and rates declined, the telephone steadily eroded the telegraph's share of the long-distance communications market.

Under the leadership of Theodore N. Vail, American Telephone and Telegraph (AT&T), Bell's parent company, was powerful enough to acquire working control of Western Union in 1910. AT&T's control of Western Union demonstrated that the telephone had eclipsed the telegraph as the nation's preferred long-distance communications medium. AT&T voluntarily relinquished its Western Union holdings in 1914 to forestall federal anti-trust proceedings. Although short-lived, Vail's administration modernized Western Union's antiquated accounting and management structure and spurred the company to replace its Morse instruments with automatic telegraph equipment.

Between 1915 and the end of World War II in 1945, the telegraph's share of the long-distance communications market continued to decline because of competition from the telephone, government air mail service, and AT&T's teletype service inaugurated in the 1930s. During the War, the Federal Communications Commission forced Western Union to divest itself of its international cable network and to consolidate with its sole remaining competitor, the bankrupt Postal Telegraph Company, two moves which weakened Western Union's long-term financial position.

Following World War II, Western Union's managers attempted to modernize the company's physical plant and to preserve a market niche for record communications. Between 1945 and 1980, the company undertook three major modernization programs, the development of analog facsimile technology, the construction of a microwave beam network to replace its wires and cables, and the launching of communications satellites. Although these systems were technologically successful, they failed to reverse Western Union's declining market share with respect to the telephone; by 1990, Western Union was defunct except for its money-transfer service.

Telegraphs in Asia and Africa

The first telegraph in India, constructed by two British army officers, opened in 1851. During the 1850s, the British government encouraged the construction of a government-owned telegraph network to link the major trading and political centers, and by 1856 India had some 7000 km of telegraph line and 45 offices.

The French telegraph network in Indo-China was also an instrument of colonial control. France began telegraph construction in 1861 and by the turn of the century the Indo-Chinese network comprised about 12 000 km of land lines and cables connecting over 200 offices. After 1880 the colonial powers occupying Africa built land and cable networks to connect their possessions with the home countries. The Indian, Indo-Chinese, and African telegraph networks were primarily instruments of imperial control and only secondarily commercial systems.

The Chinese government regarded telegraphy suspiciously, as a tool of the Western powers to gain control of their country. During the 1860s, Russian, British, and French entrepreneurs and government officials began pressuring China for telegraph

concessions. Chinese officials resisted until the 1870s, when they granted foreign companies limited franchises to build telegraph lines. In 1881, the government established an Imperial Telegraph Administration to build and to operate a national network, but officials continued to resist the wholesale construction of foreign-owned telegraph lines. However, several European countries used the Boxer Rebellion of 1900 as a pretext to extract political and economic concessions, including the right to build telegraphs, from the weakened Imperial Chinese government.

Whereas Chinese government officials sought to shield the country from foreign influences in the second half of the nineteenth century, in Japan the Meiji Restoration of 1868 brought to power an elite eager to modernize the country along Western European lines. Japan's new rulers embraced the telegraph and hired a British telegraph engineer in 1869 to build a line between Tokyo and Yokohama and gave landing rights to a Danish cable company. By 1872, Japan enjoyed direct telegraphic communication with Europe. During the next two decades, the Japanese telegraph network expanded rapidly. By 1891, Japan had over 400 telegraph offices connected by nearly 12 000 km of wire.

Submarine Telegraphy

The successful development of submarine telegraphy between 1851 and World War I established an international communications network and helped Western nations to pursue their imperialist and commercial ambitions in Africa, Asia, and Latin America. From 1850 to the early 1870s, engineers confronted and solved several problems in submarine telegraphy: insulation, cable-laying ships and equipment, signal distortion and attenuation, and sending and receiving apparatus. British scientists, engineers, and entrepreneurs played leading roles in all four areas.

In 1851, a British firm laid the first successful undersea cable between Dover, England, and Calais, France. British and American entrepreneurs and government officials soon began exploring the feasibility of a transatlantic cable. In 1856, the American Cyrus Field and the British telegraph engineers John Brett and Charles Tilson Bright headed a group of investors who started the Atlantic Telegraph Company. The company received subsidies and naval support from the American and British governments. After two failures in August 1857 and July 1858, the company successfully laid a cable between Ireland and Newfoundland in August 1858. The cable failed, however, after a few weeks of weak and intermittent signals. The 1858 cable failure, the straitened finances of the Atlantic Telegraph Company, and the American Civil War (1861–65) all combined to delay a renewed attempt until 1865. Under the leadership of John Pender, the newly formed Anglo-American Telegraph Company successfully laid two cables in July 1866, marking the start of uninterrupted electrical communication between the two hemispheres. During the last third of the nineteenth century, the Atlantic cables were instrumental in establishing global markets in news, agricultural commodities, and financial securities.

During the late 1850s and 1860s, British telegraph engineers and government officials sought to connect Britain with its possessions in India, southeast Asia, and Australia. In 1870, they successfully laid a cable from England through the Mediterranean, Red, and Arabian Seas to Bombay. In 1872, an extension from India provided direct telegraphic connection to Singapore and Australia. Between 1870 and 1914, several American and British cable companies competed for the telegraph business of the Caribbean and Latin America, a competition which mirrored and fueled the general commercial rivalry between the two countries in the region.

On the eve of World War I, about 500 000 km of undersea cables existed, over half under British control and one-fifth under American control. France, Denmark, Germany, and The Netherlands accounted for the remaining cables. This global submarine cable network helped Western nations to attain economic and political dominance of Asia, Africa, and Latin America. During World War I, British leadership in cable and wireless communications played an important role in the Allied victory over the Central Powers.

During the 1920s, demand for international communications boomed and the submarine telegraph industry reached its peak. Furthermore, AT&T introduced a major technological advance, inductively loaded cables which increased message-handling capacity by a factor of five. Western Union installed the first inductively loaded cable in the Atlantic Ocean in 1924, and the new cables ensured that submarine telegraphy would occupy a central place in global communications over the next several decades. However, economic depression and World War II between 1930 and 1945 reduced demand for international communications generally.

After World War II, two new technologies, telephone cables and satellite communications, converged to make international telephoning easier and cheaper, and hence to render submarine telegraphy obsolete by 1980. AT&T laid the first transatlantic telephone cable in 1956, and by 1983 seven transatlantic cables provided over 11 000 voice circuits. During the 1970s, satellite communications reached maturity, and by the early 1980s satellites provided about 50 000 voice circuits. The installation of digital fiber-optic cables during the 1980s increased the number of international telephone circuits by an order of magnitude and reduced greatly the cost of overseas telephone calls.

Abstract

This article explores the telephone's far-reaching impact on society, democracy, and geography from its inception in 1876 to the present day. The telephone has facilitated the rise of numerous occupations and industries ranging from secretaries and technicians to the distributed sales and telemarketing industries. The telephone has also influenced geographical dispersion, allowing people to physically isolate themselves while always being a phone call away from human contact. Telephones and mobile phones have also revolutionized the way people socialize setting the stage for a potential era of perpetual contact.

Since the invention in 1876, the telephone has become, literally, a fixture of everyday life throughout the industrialized world and much of the developing world as well. It is so commonplace that only its absence becomes noteworthy or even a topic of notoriety. Too easily forgotten by laypeople and scholars alike is the miracle of being able at any time to place a call to any other subscriber worldwide. Compounding the miracle is the fact that so many of these calls are done wirelessly and, increasingly, while multitasking. The enormous value of the telephone can be readily appreciated if one considers the plight of a villager who wants to know if there might be work available in a nearby town, or who needs to summon aid for a sick family member.

Also easily overlooked are the ramifications of this global connectivity. By allowing us to transcend a variety of physical and social barriers, the telephone has led to a complex set of dispersed personal and commercial relationships. By any measure, the telephone has dramatically altered the social landscape. Cars and airplanes were adumbrated respectively by horse-drawn vehicles and birds. Yet, in human imagination the power of real-time interactive oral communication over great distances had been a power reserved exclusively for divine beings. Given this godlike power of the telephone it is little wonder that it has been one of history's most successful inventions. Little wonder, too, that some of the earliest experiments with it were designed to ascertain whether the telephone could be used to communicate with the dead. (Perhaps not entirely regrettably, the answer is that it cannot, though efforts continue to be made to use it so.)

Global and Microcoordination

Today, for about 5 000 000 000 people, the act of making or receiving a telephone call is a normal, often daily, occurrence. (Perhaps another billion, at the other end of the development spectrum, have never used a telephone.) Nearly all settings become appropriate for using mobile telephones, and phone calls and messaging activities have invaded even sacrosanct occasions such as funerals. For rapidly growing numbers of people worldwide, the mobile telephone has become the data port through which text messages, microblogging services such as Twitter, e-mails, and documents can be exchanged. Add-on services such as location-aware monitoring accrete new layers of information on the quotidian physical environment. Given the commonplace quality of the ordinary telephone it remains hard for us to delineate the full spectrum of the telephone's ramifications throughout global societies and the interior world of individual psyches.

Although the telephone has numerous cumulative macrosocial consequences, most of them are predicated on its ability to support social interaction. An essential aspect of the telephone is its ability to allow coordination among geographically dispersed (or even locally concentrated) people. Numerous studies demonstrate that the telephone promotes business, sociality, democracy, and information flow. For those who are physically handicapped or otherwise constrained, it opens vast arrays of contacts. (It is interesting and perhaps surprising to note that the telephone has increased greatly the social contacts and informational resources for the deaf, via TeleTYpewriter (TTY) interfaces. This quality is particularly gratifying given Alexander Graham Bell's original interest in helping the deaf.)

The telephone allows convenient management over distance, and via messages, asynchronously. Upon its basis, extraordinarily large enterprises can be established and effectively controlled. As a corollary, those who would otherwise have greater independence find themselves circumscribed by those (sometimes literally) above them. The telephone has enabled the rapid conduct of large-scale financial transactions and has greatly assisted the formation of capital markets. The mobile quality of the cellular telephone has led to the phenomena of so-called 24 by 7 availability.

A collateral effect is that digital telephonic technology, including voice-mail systems, has been partly responsible for the elimination of huge numbers of middle managers and support staff throughout American industry. Ironically, many of these positions were created in the first place to deal with the communication flood created by the analog telephone. This picture is also influenced by the answering machines, which of course allow the conveyance of telephone messages without human intervention. In former times, self-respecting managers, professors, or other professionals would be reluctant to conduct their business without having a secretary on staff. (Indeed, much effort necessarily went into 'faking' the existence of a secretary to act as an intermediary.) Today, for many professionals, having a secretary would seem to be not only wasteful but also an indication to their clients that they are out of touch with best current practices.

The proliferation of digital messaging technology also affects the tenor of professional events. For instance, it used to

be the case that at a conference or symposium, the break-time would be used for social interaction and enjoying the 'here and now' aspects of the conference venue. Nowadays, however, attendees rush outside to use their mobile phones in an attempt to collect messages and return phone calls. In another context, the mobile phone and pager has led to a new form of social effrontery. While seemingly engaged in conversation, one coolly glances down and scrolls through messages of one's communication device, all the while nodding sagely as if heeding every word uttered by one's interlocutor. These are a few of the many faces of what Kenneth Gergen (2000) has termed 'absent presence.' People are seemingly at an event or socially engaged, but their attention and mental focus is elsewhere.

Telephones, especially mobile phones, increase the pace and efficiency of life. They also allow more flexibility and individual efficiency at business and professional levels and at those of family and personal life. Moreover, people can take action to allay the feeling they are not accomplishing enough. People can harness spare time, or time previously spent in tasks that do not require much attention (for instance, waiting on a shopping queue) to plan and coordinate with others, get information, or even shop remotely by phone while they shop in person. On the other hand, those who treasure respite may find themselves pressured to replace otherwise excusable isolation with productive tasks. Once upon a time, being aboard an airplane excused an executive from having to interact with colleagues. No more, for the satellite or Wi-Fi enabled telephone now follow even at 6 miles high; nor are the seashore and mountaintop beyond their reach. An age of perpetual contact, at least in potential terms, is dawning.

Despite the many advantages to having the telephone available any time and anywhere, there are drawbacks to it as well at both the individual and social levels. The telephone can be a minor irritant or a conduit for crime. In terms of the former, many social critics of the late nineteenth century expressed irritation at the way the telephone seemed to destroy the orderly pace of life, the considerable pleasures of social propriety and as well those of solitude and reflection; the target has remained lucrative, and the frustrations of telephone use and abuse remain a staple of the screen, both large and small. The telemarketing solicitation, of which there is a rising tide, is also an oft-remarked-upon irritant. Telemarketers themselves use market research, so it is no accident that their calls seem to arrive at dinnertime or other exquisitely inconvenient moments. More serious, though, is that there are a large variety of swindles – some of which even use computer-aided dialing schemes – that prey especially on those with the least social resources. Stalking by telephone and obscene phone calls to both men and women are also serious problems. On the other hand, with advances in technology that give call recipients greater power to control access to themselves (such as increasingly popular caller-identification services) people are better able to manage their communication environment to suit their individual tastes and needs.

The increasingly nuanced technology available to callers and callees demands ever greater sophistication to achieve a flawless performance of the choreography of communication. Think of the dilemma of a shy but sedulous teenage boy who wants to ask a popular girl to the school prom. Presumably he would not want to leave a trace on her caller-identification record of his 40 or so attempted calls before finally reaching her. Suffice it to say that, sadly, it appears that there is an iron law of telephone contact: people generally get the most calls from those whom they would least like to hear, and vice versa.

In all, though at times a source of irritation and adroit tool of criminal activity, the telephone has proven to be an important factor in increasing the pace, scope, and intensity of business and management operations while simultaneously lowering the cost of engaging in these activities. It has had a parallel effect on people's levels of social interaction.

Geographical Distribution

The telephone has influenced substantially the distribution of people across the physical landscape. On the one hand, the telephone has allowed the massive vertical downtown urban center to survive then thrive. Without the telephone, the skyscraper would have been most difficult to build and manage. Further, it would be difficult for the structure to maintain its usefulness to its denizens without the telephone.

Some claim that the telephone has enabled one particular form of geodemographic dispersion, the suburb. However, detailed studies of transportation system development indicate that the telephone was not an important factor in this remarkable internal migration. Still, the telephone does allow many in rural locations to participate in business and social relations in a viable way, which without the telephone would not be possible. At the same time, those in extremely low-density areas have persistent difficulty getting even minimal telephone service; the situation is exacerbated by the fact that this populace is generally poor and remote from economic opportunities. This, unfortunately, is a social problem that will endure for decades. The telephone, though, has allowed those who choose isolation – and such people are often drawn from the middle and upper strata of society – to enjoy it without having to forego ready communication. Some seek to 'get away from it all' but still want employment as consultants, or at least to stay in convenient contact with friends, family, and emergency services.

Economic Development

It has long been an article of faith that the telephone promotes economic development and social welfare. This belief has had powerful repercussions on national telecommunications policies worldwide. These have ranged from subsidized rates for the poor, subsidized rates for everyone, and special incentives for telephone companies to modernize their systems or physically extend their services to remote areas. Certainly there has been a strong association between telephone lines and economic growth, particularly, as Hudson (1984) has shown, in developing countries. Researchers have demonstrated a logarithmic relationship between main telephone lines and national income on a per capita basis, although the direction of the causal arrow has not yet been established.

What is not in doubt is that the telephone itself fosters employment growth, not the least to serve itself as an industry.

In the early days of mechanical switches, when telephone systems were growing dramatically, it was speculated that within a generation all young boys in America would have to be employed simply to connect phone calls. Although this scenario never materialized, phone companies have traditionally been enormous consumers of manpower, and are usually one of the largest employers of a region. Traditional telephone companies everywhere, though, are for the most part looking for ways to reduce their traditional workforces, heavily concentrated in jobs of installation or as operators. They are replacing vast numbers of these workers with smaller numbers of software engineers and technicians.

Even as the workers per 1000 telephone lines decreases worldwide, employment in the wireless telephone industry has mushroomed. In many cases, the growth in the mobile phone sector has far surpassed the cuts in the traditional wireline companies (many of which were formerly government ministries of Post, Telegraph, and Telephone services). As the expense of laying copper wire is far grater than erecting a radio tower, many people in developing countries are gravitating to mobile phones simply because they can get them more quickly than wireline ones. It is my sense, based on limited studies, that because the mobile phone is more flexible and can be used in more places, its economic impact will be still greater than that of the growth of its tethered counterparts.

Telephones can have other economic effects: they ease the job prospecting process directly, increasing economic efficiency by making it easier to change jobs. Also, by using the telephone as a sales tool, consumption is stimulated, which leads to job creation and economic growth. Staffing the sales force alone of course means that jobs will be created.

Although much of the prior discussion focused on macroeconomic effects, it is also worth mentioning the twofold microeconomic impact of the telephone. First, it allows individuals to run their own business, often from their home or voice mailbox. Thus, it encourages small enterprises. Yet, it also encourages large-scale enterprises as well since it allows firms to capture the benefits of large size without excessive coordination costs as discussed above.

Policy and Politics

Due to its ability to connect quickly to remote areas, the telephone has helped foster national integrations. At a structural level, it also serves to centralize exercise of political authority while concomitantly circumscribing regional centers of power. Notwithstanding this structural aspect, the telephone has something of a reverse consequence for individual political empowerment. In this regard, Ball (1968) and Aronson (1971) argue that the telephone has been a politically democratizing instrument. There is much to this viewpoint, and studies have shown that, controlling for levels of economic development, in Communist countries of Eastern Europe there were equivalent numbers of TV sets when compared with their Western European counterparts. However, there were drastically fewer telephones. The presumed reason for this maldistribution is that the telephone enables two-way communication, whereas the TV allows controlled information to be sent in a one-way direction from a centralized source to a passive mass audience.

The important role the telephone system could play in controlling the populace has not been lost on governments. In the late nineteenth century, France wanted a centralized, governmentally controlled telephone system because authorities anticipated that rebels might otherwise be able to seize control of it during an uprising. During the Soviet communist regime, the absence of telephone books in Moscow was legendary. Telephone tapping is a long practiced art that has been used to fight crime and enemies of the state.

Revolutionaries as much as police recognize that the telephone is the body politic's nervous system. Hence, it is a universal target for those seeking to subvert or protect the government. Lenin directed that the telephone and telegraph offices be initial targets of his Bolshevik seizure of power. As a contrary example, we point to the August 1991 coup attempt against Mikhail Gorbachev and his government. The plotters failed to seize the telephone system. Consequently, the anti-Communists were able to use it to rally themselves. Boris Yeltsin and his supporters, barricaded in the Parliament building, were able to make and receive calls from around the country and the world; they used this power to marshal and coordinate support. A report on the Russianet even claims the parliamentary defenders were able to phone in their food orders to the Moscow Pizza Hut. The telephone facilitates the management of political campaigns and the operation of political organizations.

For well-organized campaigns, the telephone bank has become an important element in any contest. They can also be used to generate otherwise lethargic public interest in issues. In the United States, a neologism has been created to describe the abuse of this process. The term is 'astroturfing,' in honor of the artificial grass of the same name. Astroturfing is the process of using telephone banks to create the incorrect impression among politicians that there is a 'grass-roots' swell of public concern about an issue when in fact there is little or none. Instead, the outpouring of opinion on the issue had been catalyzed by a small group of telephone operators who 'pipe through' a citizen to her representative's office to recite a prepared message. This example provides further demonstration of the principle that telephone technology has an impact that is governed largely by the motive of the user.

Societal Aspects

Traditional sociological variables of age, social class, socioeconomic status, gender, and race/ethnicity influence people's relationships with the telephone. Young people are generally much more likely to adopt new technology than their older counterparts. Material resources, as measured by income, also have a noteworthy effect. Predictably, those at the very bottom of a society's income distribution are least likely to have telephone service. More surprisingly, as shown by Katz's (1999) research, people in the third income quartile are disproportionately represented among purchasers of enhanced telecom services. This may be because these services are perceived as entertaining or of high prestige. This noteworthy trend occurs in both Europe and the US; whether it obtains in other regions is unknown. Subsequent studies have confirmed this

relationship, and even suggest that it is extensible to developing countries such as China (Katz, 2010).

Since its inception, there have been speculations about the small-group and social interactional consequences of the telephone. Marvin (1988), in her path-breaking study of the social reception of the telephone (among other nineteenth-century electrical technologies), demonstrated that concerns over the impact of the telephone were reproductive of those of the larger society. Among these were the erosion of family authority, race, and social class barriers, and sexual and social propriety. Also of substantial concern was disrespectful and deceitful behavior. Victorian-era Americans believed, justifiably, that the telephone reduced social cues ordinarily conveyed in the richer channels of face-to-face interaction and written correspondence. By masking cues, such as the location and social status of the caller, the telephone denied important cues to assist in making judgments about the interlocutor. Thus, it would be easier to violate social and legal codes. These concerns remain substantial even after a century of telephone use, and are born anew with contemporary communication technology such as the Internet.

The telephone plays a role in the conduct of gender relations and in the pursuit of sexual gratification. In contemporary, often suburbanized society, the telephone has become an important means by which teens socialize themselves in an historical period when they are defined as problematical non-adults (Wynn and Katz, 2000). Commonly, women run the 'social work' of maintaining family links and social schedules via the telephone. (All other things being equal, when both a man and a woman are in a room together, a woman is twice as likely to answer a ringing phone.) Rakow (1992) has documented the important role the telephone plays in women's relationships, and the ways it provides support for their independence despite various constraints and provides them with social resources they need to pursue their relationships and goals.

As in other areas, the telephone can enhance coordination in people's search for partners. The telephone's role in abetting prostitution has long been noted. (Indeed, a term-of-art, 'call-girls,' clearly refers to the role of the telephone.) While it is impossible to capture precisely the temporal, economic, or organizational magnitude of the telephone's role in the commercial sex industry, plainly large sections of the yellow pages and of urban newspapers are devoted to presenting this information in a slightly hidden argot to knowing patrons.

The telephone can also serve as a less direct conduit for sexual expression. Indeed, the conduit of remote interactive sex is an entirely *de novo* mode of expression enabled by the phone. The remote as well as the disembodied aspects of a telephone call can have its sexual appeal, and in this regard one hardly need mention the candlestick design that characterized phones for a half century. By relying on its aural and fantasy capabilities, it can also serve as a sanitary substitute for in-person sex. Recognizing this pent-up demand, an entire industry of 'pink services' has sprung up in any country where it is allowed. Definitive data as to its size are difficult to obtain, but an instructive data set can be derived from the Austrian experience. Austrian law had forbidden phone sex historically. However, in 1991, a revenue-sharing arrangement was established so that offshore companies could benefit from premium international telephone tariffs. The Dutch Antilles became a center of such 'pink services,' and numerous companies began placing ads in Austrian newspapers giving their Antillian numbers. The results were dramatic and instructive. For all of 1990, the total duration of minutes of calls to the Dutch Antilles from Austria was exactly 13 050. For the first 9 months alone of 1991, the number of minutes of calls from Austria to the Dutch Antilles exceeded 1 600 000.

Not all telephone sex is predicated on a financial arrangement. Many millions of obscene calls are reported annually to authorities. Both men and women make obscene phone calls to obtain erotic stimulation from the reaction of their shocked victims. These types of calls seem to occur throughout the world wherever a telephone system is present. As a case in point, within 6 months after the first automatic telephone network was installed in Papua New Guinea, an obscene phone call was reported to authorities. A third class of sexually oriented telephone calls is neither commercial nor inflicted on victims, but rather occurs by mutual consent. For decades, lovers have enjoyed erotic phone conversations, and the topic receives substantial treatment in literary and cinematic formats. Nevertheless, seldom has public attention to this private aspect of human behavior risen to the heights it did in 1998. As part of a larger relentless investigation, an incident of sexual gratification via telephone between US President Bill Clinton and his White House aide, Monica Lewinsky, was given protracted national media attention and related to Congress in an official report. Thus, presidents and perverts alike serve to demonstrate that the telephone, like every other communication technology – from the video camera to the car, and from the printed book to the web-enabled mobile phone – can be used by people as a context for sexual excitement and fulfillment.

Another striking aspect of the telephone is its use as a tool of personal empowerment. With emergency phone boxes set up on campuses, and especially with the mobile phone, people can feel safer in public areas. It has expanded the places and times that people, especially women, can go to a variety of places, thus increasing people's freedom and mobility. It also permits parents to expand the privileges they give their children in terms of when and where they can go. This has the intriguing result of both increasing and loosening parental control.

The telephone also enhances individual autonomy by allowing people to live more successfully by themselves. Yet it preserves instant access between those experiencing a medical or police emergency and a variety of support services. In addition, a substantial variety of community and psychological services are available at any hour and often with complete autonomy.

As with any technology, the use to which it is put is influenced by the motives of the human user. Just as not all people are good, neither are all purposes to which the telephone is put benign. The telephone has offered new venues for monitoring individuals, invading their privacy, and harming them materially or psychologically. In terms of monitoring, the wireless revolution, particularly as it intersects with the telephone, is increasingly affecting all aspects of social interaction, from the conduct of relationships to the receipt of medical care. These technologies will not only be used to deliver services but as well to monitor the individuals. In the past telephonic monitoring has targeted parolees and the elderly. The number of citizens who are regularly and passively tracked will be increasing; this

will be done through the data collected by systems used to regulate mobile phones and intelligent highways. Already mobile phone records are being used in civil (e.g., divorce actions) and criminal cases (e.g., the apprehending of kidnappers).

The telephone also gives individuals tremendous powers to affect others' lives at a distance. Though often used in pranks and practical jokes, the telephone has also been used to inflict protracted harassment and terror on others. Such practices include spreading malicious rumors, making harassing calls late at night, and even concocting identities in order to manipulate or frighten someone. In one case, a young girl pretended to be a nurse, and in this guise reported (falsely) to another girl that her lab test results indicated that she had AIDS and was pregnant. The girl victim attempted suicide and disaster was only narrowly averted. The culprit was caught using caller-ID.

Turning our attention to the underpinnings of social life, Fischer (1992) found that a social psychological effect of the telephone was that it seemed to accelerate the pace of social life. His classic study, *America Calling*, found that the spread of the telephone in the US reduced isolation and increased social contact. A concomitant finding is that a good proportion of telephone users experienced anxiety or 'communication apprehension.' Many citizens also feared excessive social contact, becoming the subject of telephone gossip, and being subjected to unwanted calls. However, he found no support for more extreme claims that it brought people to a constantly heightened sense of alertness and anxiety over the potential summoning outcry and the emergence of 'psychological modernity,' that is, the contemporary sensation of free-floating anxiety and dehumanization. Rather, he concludes that on the whole, people readily and comfortably assimilated the telephone into their lives. They used it as "the conscious product of people employing things, not of things controlling people."

Technological Convergence

It is impossible to speak of today's telephone exclusively in its formerly traditional wireline configuration. Mobile phones, discussed below, are but one aspect of this telephonic reconfiguration; it extends to all aspects of voice communication. One salient aspect is the way people manage their calls. For instance, in the US, the majority of telephone subscribers also have some form of answering machine. This device changes how people use their phones, e.g., to monitor before picking up the receiver, and which in turn affects the behavior of the caller ("I know you're there! Come on, pick up."). Having the telephone answered by a machine was until 1987 seen by the majority of the US population as an act of rudeness to callers. It was emblematic of the fear that 'robots would take over,' and that people were losing control over their daily lives. (This also ties into the above point about the importance of having a secretary to handle one's calls.)

Today opinion surveys show that the majority judges it an important courtesy that should be extended to callers. Some even go so far as to say that it is rude not to have an answering machine or voice mail. Still, the answering machine/voice mail is but one of the ever-multiplying ancillary services that are being added to the formerly black 'one-size-fits-all' telephone. Together they are changing what a telephone is and how it is used, as well as the subterfuges that are used to work around the telephone's expanded capabilities.

Even as the telephone becomes more powerful and capable, it is becoming tetherless. Not only is the home phone increasingly likely to be cordless with reception to a ½ km from base, but people are increasingly subscribing to mobile telephone services that will allow them to range across continents. Moreover, some people are abandoning their wireline phones entirely; in the US, more than 20% of subscribers have done so already and their numbers are increasing. Among other things, this trend means the loss of geographical meaning to area codes, something once deemed an important marker of physical identity, but now increasingly relegated to the category of trivia or arcana.

Computers themselves are increasingly encompassing the features of the telephone, becoming Internet phones and answering machines and voice chat messaging units. Personal digital assistants are beginning to act as both mobile phones and portable computers. For their part, cell phones are becoming more like computers. The age of the 'smart phone' could mean that the computer platform will for most people be subsumed within a portable personal device. Abilities are becoming intermixed, that is, telephone conversations can occur virtually anywhere with anybody via any machine. One consequence of this technological advance is that, without too much hyperbole, it appears that there is arising a new sense of 'perpetual contact.' This new state will allow better coordination, improved business operations, and enhanced kin and social relations. It will also introduce new conflict over the appropriated norms for, and possible constraints on, people's public behavior. To cite an instance, there are now mobile phone–free rail cars and restaurant sections.

Already, however, the proliferation of mobile phones has created a brouhaha over their use in public places, most especially while driving cars. Though some of the controversy revolves around manners and appropriate levels of sensitivity, the larger issue of the use of mobile phones and conduct in public places is only beginning to be addressed. It remains an unsolved puzzle for social scientists and the architectural profession to create public spaces that can amenably coexist with privatizing mobile telephonic behavior. However, the much more powerful issue is the question of safety. Mobile phones mean not only that lives can and will be saved but also that – because there are those who elect to use it while driving – lives will be lost. Sadly, there is a growing toll of people killed by mobile phone using drivers. Those who are affected by such tragedies will continue to produce legislation restricting the use of mobile phones in cars, perhaps in other areas as well.

The Telephone as Synecdoche for the Modern Condition

The telephone has had a substantial impact on the structure and quality of human existence, from business to sex, and on the conduct of war and peace from the international to the intrafamily level. Never has so small a device been used so easily by so many to do so much to so many.

The use and abuse of the telephone encapsulates and expresses the dimension of social scientific perspectives on modern life. What happens in the larger canvas of life is reproduced within the ambit of life on the telephone. The telephone's impact stems from the inherent qualities of a technology that allows easy, inexpensive real-time interaction by voice over both short and great distances. People have investigated aggressively and exploited this technology's potential. Through this unrelentinfg effort, there has been an isomorphism between what the technology can achieve – as its capabilities become more sophisticated – and the needs and desires that exist within mankind's biological and social framework.

The telephone system has been used in ways as broad as the human imagination, many times in ways that were never envisioned (or were even opposed) by telephone company system designers and marketers. Telephone systems have been used to broadcast operas and provide wakeup, dial-a-joke, and dial-a-prayer services. Psychological and emergency services, astrological advice, and interactive matchmaking services are among its staples. Users themselves have created a variety of 'work-arounds' to beat the telephone system (e.g., tone-generating boxes that allowed callers to bypass toll charging mechanisms). None of these uses or innovations was fore-ordained. Rather, as shown by Coopersmith (1991), far from a calculated manipulation of telephone company executives, some innovations as enormously successful as the fax and answering machine were at various points in their development opposed and thwarted by telephone company executives.

No dictator, the telephone has become a servant to those pursuing profit and pleasure. The picture after more than a century and a quarter is quite unlike those sketched originally by hand-wringing dystopians, such as Mark Twain. These critics saw the technology as depleting social capital, killing social relationships, and inducing depression (a view similar to today's critics of the Internet).

On balance, the telephone has clearly done far more to liberate humanity than enslave it. This observation is not meant to downplay the harm that can be and is inflicted telephonically. Like two other communication technologies – the airplane and the car – the telephone can be used for both good and evil. It can be used to wreak suffering and terror; it can be used to carry messages of love, hope, and redemption beyond the vast oceans. In this context, then, we should recall the lessons of the Bible and the Greek myths that even the existence of a powerful god is not without frustration.

Television: General

Jostein Gripsrud, University of Bergen, Bergen, Norway

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Television has been the dominant mass medium in most Western countries since the 1950s. It has been studied in a great variety of ways, in a number of scholarly disciplines, from psychology and the social sciences to film studies and art history. In the 1970s and 1980s, precisely because the medium invites cross- and interdisciplinary approaches, the study of television was central to the establishment of media studies and cultural studies as new forms of scholarly inquiry and teaching on the borders between the social sciences and the humanities. This article sketches the history of research on television by presenting and discussing main issues, positions, and findings within a selection of central themes. It starts out by looking at relations between the medium as a cultural form and fundamental features of modern society, and then proceeds to map areas of inquiry such as policy/regulation, television production, the structures and contents of programs, the study of audiences and their relation to the medium, and contributions to our understanding of the specificity of the medium. A final section briefly discusses the future of television research.

Television has been the dominant mass medium in most Western countries since the 1950s. It has been studied in a great variety of ways, in a number of scholarly disciplines, from psychology and the social sciences to film studies and art history. In the 1970s and 1980s, precisely because the medium invites cross- and interdisciplinary approaches, the study of television was central to the establishment of new forms and institutions of scholarly inquiry and teaching on the borders between the social sciences and the humanities, media studies, and cultural studies. So far, there are very few if indeed any university departments exclusively devoted to television studies.

The study of television is, thus, still organized in accordance with the general divisions between scholarly disciplines and between 'schools' within (mass) communication and media studies. But especially since the early 1980s, there has also been a trend toward a form of eclecticism where it is recognized that useful work is done from a number of starting points, employing a number of methodologies and a variety of theoretical frameworks. The digitalization of the medium and the rapid growth of various web-based services have further diversified television studies both thematically and methodologically.

The Medium and Modernity

Raymond Williams suggested in *Television: Technology and Cultural Form* (1975) an understanding of television that focused on its social organization as a broadcasting medium, arguing that there is a functional fit between this form of communication and the conditions of modern society. Processes of modernization led on the one hand to centralization of resources and power, on the other to increased social and geographical mobility. Williams termed this latter aspect of modernization 'mobile privatisation,' referring to the relative social isolation of individuals and nuclear families literally and metaphorically 'on the move.' Broadcasting was simply a highly adequate institution in this social situation. It makes immediate distribution of necessary information to all citizens possible, and efficiently contributes to the construction of the 'imagined community' (Anderson, 1983) of nation-states.

Historical research has demonstrated that television technology in itself had other possibilities as well. It was already envisaged in the nineteenth century as a new form of two-way communication. Companies such as AT&T experimented with 'picture-phones' in the 1920s, and amateurs started constructing simple transmitters and receivers. Also, the idea of video surveillance was explored at this time (Allen J., 1983). A more serious alternative to broadcast TV was television as a theatrical medium for collective, public reception. Nazi Germany developed such a system in the 1930s, with hundreds of public television halls throughout the country (Uricchio, 1989). Most people who experienced the first telecasts of the BBC in that decade did so in restaurants, at railways stations, and the like (Corrigan, 1990).

But already in the 1880s, there is evidence that popular imagination played with the idea of broadcast TV, that is, the transmission of sound and images from some central source directly to people's homes, organized in genres such as news, education, art/entertainment, and advertising (Wheen, 1985). In the 1890s, Thomas Alva Edison and others were striving to come up with a successful solution for broadcasting TV (Sklar, 1976: p. 11), and the idea circulated throughout the Western world. All of this lends support to the idea that broadcast television to private homes is related to fundamental social structures and interests in modern capitalist societies, such as the division between the domestic and the public realms on the one hand and the need for socially and culturally integrative efforts on the other. Furthermore, processes of democratization could obviously also be served by broadcasting media since they allow for a more equal access to resources of information, knowledge, and cultural experiences.

The development of multichannel systems of broadcasting, especially via satellites and cable systems since about 1980, may thus be thought of as 'divisive' since they constitute numerous separate viewer-communities within a given nation. So-called postmodernist theorizations of television consequently

saw multichannel television's abundance of programs on offer at any time as a manifestation of a new, presumably 'decentered' social and cultural situation (e.g., Collins, 1989). While the general decline in viewer numbers for the major, regular television channels (e.g., network TV in the United States, public broadcasters in Europe) is well documented, relatively little empirical work has been done on the larger social and cultural consequences of the transition from one or a few to dozens or hundreds of television channels.

There is now a growing number of scholarly publications on the variety of online audiovisual services on offer, from YouTube to Netflix, but few attempts at empirically grounded estimations of how these developments affect structures and functions of the public sphere, social coherence, distribution of knowledge, and so forth. However, most (adult) viewers still spend much or most of their viewing time with a handful of TV channels, free-to-air or subscription channels, and watch discreet programs, possibly prerecorded or streamed over the Internet, as much as they just zap around. Hence the continued existence of 'hit shows' and newscasts competing over ratings. Most 'generalist' channels still stick to well-known genres of programming, have fairly similar newscasts, and address the same or similar issues. It can, thus, be argued that television has retained some of the socially and culturally integrative functions ascribed to it by Williams. Clearly, though, these functions have been modified, first, by multichannel satellite and cable TV, and, second, by digitalization and web-based audiovisual services.

Policies

The history of television policies starts with the attempts to regulate radio broadcasting in the 1920s. The fact that the number of available frequencies was finite led to forms of public regulation unheard of for other mass media. While most European countries decided to organize broadcasting institutions as state-owned monopolies, financed by a license fee, the United States from the beginning regarded broadcasting as another business opportunity, where profits would come from advertising revenues. The United States also had to regulate broadcasting in ways that made it a quite particular area of private enterprise. Frequencies had to be allocated to broadcasting organizations by some public agency, operating in accordance with a set of politically determined principles. The first comprehensive broadcasting legislation in the United States, the 1927 Radio Act, made clear that those who were licensed to use radio waves, were required to serve 'the public interest, convenience, or necessity' (Hoynes, 1994: p. 38). The Federal Radio Commission, which in the 1930s became the Federal Communications Commission, was therefore established. It has ever since played a pivotal role in political struggles over the development of broadcasting in America, with agendas shifting as political administrations have come and gone. Key issues have been the ways in which competition is to be ensured with a necessarily limited number of actors in the market place, and whether or how space and resources are to be provided for noncommercial, public TV. Underlying both issues is the question of what the notion of the 'public interest' which broadcasting is to serve actually means. The scarcity of frequencies lost much of its importance as a basis for regulation with the introduction of satellite and cable television and even more when the, in principle, infinite space of the Internet became a channel for multiple TV-like audiovisual services. Trying to keep up with these changes, the European Union in 1989 adopted its Television without Frontiers directive, which after having been revised in 1997 was finally replaced by the Audiovisual Media Services Directive in 2007. The latter covers both linear (traditional broadcast) and nonlinear (on demand) audiovisual services, but regulations are lighter for on-demand than for linear services.

Regulations and the forms of funding clearly influence program output and thus the medium's social functions. Williams (1975) demonstrated in a simple quantitative comparison the differences both between programming in commercial and noncommercial channels and between the television systems in the United Kingdom and the United States. In the United States, public channels were without broadly popular drama or other entertainment, while network TV was lacking documentaries, one-off dramas, educational programming, and so forth. The result was a polarized system where the majority of viewers would in practice not encounter certain types of programs that might be important to them as citizens. In the British 'duopoly' system, the characteristic differences between commercial and public channels were also observable, but the differences were considerably less pronounced so that the programming menu available to all viewers was more varied.

The BBC generally functioned as a model for European public service television. The definition of public broadcasting's mission formulated by the BBC's first director general, Lord Reith, was thus programmatic for most or all of these institutions – they were to provide information, education, and entertainment to the entire population at a price affordable to all. Some critical scholars, especially in the 1970s, perceived the BBC as an elitist institution basically affirming the existing cultural and social hegemony in the United Kingdom. However, when commercial satellite television arrived in the 1980s such critique partly gave way to a view that emphasized the democratic qualities of the public service television tradition. Since the mid-1980s, the threats to public service television posed by so-called deregulation of broadcasting and the expanding commercial offerings have motivated lots of research into the traditions and conditions of this form of broadcast TV all over Europe, including comparative studies that clarify considerable differences between the various national systems (e.g., Syvertsen, 1992; Raboy, n.d.).

The European Union now decides much of the premises for broadcasting policies in Europe even if this is in principle an area where member states are to retain national sovereignty. On the other hand, the EU has officially decided that public service broadcasting is to be protected. The European Council of Ministers (which includes the EU member states but also all other European countries) has done the same and also defined 'public service television' in a way that very clearly sets it apart from and in opposition to purely commercial services. The distinction is of considerable social importance: Research seems to indicate that the democratic potential of broadcasting is enhanced when it operates as a public service, and diminishes with its degree of commercialization. This

has been argued in a large number of scholarly publications over the last few decades (e.g., Garnham, 1986; Murdock, 2005). But it has more recently also been argued on the basis of hard data from a large-scale, comparative study of media and broadcasting systems in four different countries (Curran et al., 2009). The study shows that (1) the overall levels of public knowledge are higher and (2) the difference in knowledge between people with different levels of education is very significantly smaller in countries where public service broadcasting is quite strictly regulated and not funded by advertising (Finland and Denmark) than in countries with very lax regulation of commercial forces in broadcasting (the United States – the United Kingdom is placed in an intermediary position.)

Production

Research on television production ranges from studies of political regulations, ownership, and other aspects of the economics of the television industry, via studies conducted on production processes in broadcasting institutions and independent production companies to theoretical discussions of the notion of 'authorship' in the context of the necessarily collective production processes in television.

The so-called 'political economy' tradition in mass communication research has always focused on the importance of economic forces and related social structures. Prominent representatives of this tradition are Schiller (1989) in the United States and Garnham (1990) in the United Kingdom, both regarding television as part of the larger media system of capitalist societies. Networks and production companies are parts of huge conglomerates encompassing not just media and leisure industries but also any number of other branches of business. These enormous concentrations of capital exert considerable political and cultural power, both domestically and internationally. British scholars of the 'political economy' tradition have, moreover, been exploring the implications of Jürgen Habermas's theory of the 'public sphere' for our understanding of television and the media in general (*see* Public Sphere and the Media; Mass Media, Political Economy of; Information Society).

In-depth studies of television production practices and personnel are still not very many, but there has been an increasing interest in this area – now due to digitalization often seen as part of a broader field of media production – over the last few years. Cantor's *The Hollywood TV Producer: His Work and His Audience* (1971) is a classic in the field, a piece of organizational sociology charting the space for creativity in television and describing three types of television producers – the 'filmmakers,' the 'old-line producers,' and the 'writer-producers.' The often well-educated writer-producers appeared as the only group that both take the medium seriously and expect the audience to accept more ambitious shows with social 'messages.' Newcomb and Alley (1983) represent a more traditional humanistic view of textual production in their *The Producer's Medium*, based on interviews with individuals they claim have managed to leave their personal imprint on the series they have produced. Gitlin's *Inside Prime Time* (1983) is a study also of top-ranking executives which demonstrates not least the space for personal agendas and preferences when decisions about programming are made. Executives may use results of audience research that support their intuitive preferences while setting aside those that do not. A major, more recent contribution, is John Caldwell's *Production Culture* (2008), a multiple-method study which more than previous work emphasizes the role of 'below the line' laborers in the Los Angeles–based film and video industry and how these as well as 'above the line' personnel make sense of their work. This focus on the industry as a whole has left its mark on later work where the situation of both more and less skilled labor and the industry's general *industrial* nature has been underlined.

Caldwell's book is also among the few studies where an analysis of production is combined with textual analyses of products. An early example of this is a study of the independent company MTM Enterprises, which contributed to a renewal of US television drama with shows such as *The Mary Tyler Moore Show* and *Hill Street Blues* (Feuer et al., 1984). In Britain, Tulloch and Alvarado (1983) did a similar study of the BBC serial *Doctor Who*. Buckingham (1987) and Gripsrud (1995) are examples of studies that also add an analysis of audiences to the study of production and textual analysis, thus covering the entire communicative process.

Programs

Williams (1975) was the first to name and point out the importance of the way in which television's (and radio's) programs are presented as parts of a continuous 'flow.' This means, according to Williams, that the impressions and meanings of individual programs will tend to overlap and merge in the viewer's experience. Flow remains a fundamental feature of broadcast programming. The ordering of programs in certain sequences, so-called scheduling, is of great importance to any television channel. It represents a channel identity and can be used to attract and not least keep viewers for the channel's programs and ads. As Ellis (1982) pointed out, most programs also consist of *segments*, that is, sequences of up to about 5–7 min that are more or less self-contained in terms of meaning. This structure results in part from its practical advantages from a production point of view, but it is also related to the need to make programs accessible to viewers who arrive in the middle of a program. The 'program' unit is thus in a sense a troubled category, threatened by dissolution both by the 'flow' and by internal segmentation.

The limits of 'the program' as an object of textual analysis have consequently been discussed, including the problem of separating the program text from the ads that are inserted into it and the question of the status of a single program or episode in soap operas that run an ongoing story for decades (Feuer, 1989; Allen R., 1985). In practice, viewers have few problems in identifying their favorite show and distinguishing it from the ads, and a soap opera (as well as newscasts and other long-running programs) may be analyzed by way of a more or less representative sample of episodes (Gripsrud, 1995).

It is probably correct to say that most textual analyses of television have been preoccupied with questions of representation and ideology, that is, the representation of gender and

sexuality, of race and ethnicity, class, social conflicts, political issues, and so forth and how they relate to larger ideological patterns and struggles. To these ends, all the theoretical, more or less philosophically grounded, approaches in textual analysis have been applied in a variety of blends – semiotics, psychoanalysis, phenomenology, hermeneutics, and so forth. While fiction and entertainment have provided most of the material for such work, also newscasts, talk shows, and documentaries have been analyzed, often interestingly demonstrating the ways in which such 'reality programming' is actually constructed in accordance with certain textual traditions and principles rather than relating directly the structures of external reality.

The most prominent of social science traditions in the field of program analysis is so-called quantitative content analysis, which defines certain elements of content and then proceeds to count their occurrences, most often across large samples of programs. Typically, the elements counted would be violent acts, sexual innuendo, women in powerful positions, and so forth. Such research may provide overviews of developments over time in certain dimensions of programming or suggest the extent to which certain portrayals of social categories or issues have a dominant position in the total program output or in a certain genre. A prominent example of large-scale quantitative content analysis of television programs is that conducted by Gerbner and coworkers in the late 1960s and early 1970s, the results of which were central to the formulation of the so-called 'cultivation theory,' that is, a theory of television's long-term consequences for people's world view (Gerbner, 1973). Their analyses indicated that (US) television, across genres and individual programs, presented a systematically distorted view of social realities in a number of areas such as family life, work and social roles, aging and dying, crime, and violence. Correlating content analysis with opinion surveys then seemed to suggest that viewers, especially heavy viewers, accepted this distorted view of social conditions as true.

Audiences

In line with the general history of research on modern mass media, worries over how the new medium affected especially children and adolescents were important starting points for the first studies of television in the 1950s. For example, Maccoby (1951) concluded that the medium undermined communication within the family, even if it made family members spend more time together. The same researcher later tried to show that television viewing had a negative 'escapist' function for children who were lacking real-life satisfactions (Maccoby, 1951). Studies such as these were fraught with both conceptual and methodological problems, and marked by a prejudiced, negative attitude to the medium. Any viewing of dramatic fiction would for instance tend to be counted as 'escapist,' reflecting a somewhat shallow understanding of the uses of fantasy and art in general. Around 1960, large empirical projects both in the United Kingdom and in the United States tried to estimate the social and cultural implications, especially for children, of the nationwide introduction of television (Himmelweit et al., 1958; Schramm et al., 1961). The everyday lives of children in communities with and without television were charted in surveys and compared. The findings of these studies were quite complex and did not give a totally negative view of the medium's social and cultural role.

The aforementioned 'cultivation theory' – or, rather, hypothesis – is basically in line with critical theories of the structural, long-term power of the media to define social reality in ways that harm various disadvantaged social groups. Throughout the 1970s such perspectives on television were theorized and significantly renewed in work conducted by researchers at the Centre for Contemporary Cultural Studies at the University of Birmingham, UK. Hall (1973) applied concepts from semiotic theory to the process of communication, speaking of production as a moment of 'encoding' and reception as a moment of 'decoding,' thus theoretically demonstrating the possibility of complications in the 'transfer of messages' that were not simply due to 'noise' or misunderstandings. Hall suggested three main types of 'readings' of television programs – 'dominant,' 'negotiated,' and 'oppositional,' that is, acceptance of the program's 'message,' partial agreement, and critical rejection. An empirical study of groups of viewers conducted by Morley and Brunsdon (Morley, 1980) demonstrated how social class and political convictions might shape audience attitudes to television programs, making some groups more critical than others. In the wake of this study, audience research within or close to the British cultural studies tradition has repeatedly demonstrated how varied interpretations and evaluations of programs might be, both within and between social classes, races, genders, and nations. They have also described how television viewing is inscribed in people's everyday lives and the routines and power struggles that prevail there (e.g., Morley, 1986; Seiter et al., 1989), how this came about historically in a wider social and cultural context (Spigel, 1992) and, somewhat more abstractly, how television viewing has deeper social functions related to its psychological functions for viewers (Silverstone, 1994; Ellis, 1999) (*see* Audiences, Media). More recent research on television audiences, employing a variety of quantitative and qualitative methodologies, has focused, e.g., the cultural diversity of audiences in increasingly multicultural societies and there has been, not least, increased attention to various forms of audience participation in programs and audience influence on program output that have become available particularly through digital technologies and online "fan" communities tied to particular genres and series. An important contribution to this direction of research was Henry Jenkins' *Convergence Culture* (2006).

Medium

Much scholarly writing and various sorts of research may be categorized as contributions to an understanding of television's specificity as a medium in terms of the ways in which it represents reality outside of itself and the ways in which it relates to its audiences. One of the first contributions of lasting significance on the latter theme was the article by social psychologists Horton and Wohl (1956) in which the authors coin the term 'para-social interaction' in a discussion of the 'intimacy at a distance' characteristic of the relations between viewers and television characters such as talk show hosts. The term refers to the way in which viewers tend to

establish pseudo-dialogical relations with television characters, 'talking back' to them, and so forth. These practices set television apart both from film and radio, and reflect the particular type of intimacy associated with this domestic audiovisual medium. They can, besides the domestic location of sets, be tied to the normal size of the screen, which renders close-ups of human faces close in size to those of interlocutors in the same room. Importantly, television's 'talking heads' often address viewers directly ('you'), simulating real conversation also in its preferred styles of speech. These features are shared by radio but have an even stronger effect when combined with moving images.

Furthering this line of thought, Meyrowitz (1985) argued that television has contributed significantly to a series of important changes both in the public sphere and in the relations between people in general. Television has moved politicians and other public figures closer to the rest of the population by presenting them in close-ups and settings that make them appear more 'ordinary.' A new way of appearing in public has thus developed, in which the public or private distinction has become blurred. Meyrowitz terms this 'middle-stage' behavior, referring to Goffman's (1959) distinction between a 'front stage' and a 'back stage' set of conventions for self presentation. This has radically altered the conditions for all sorts of rhetorical practices. Moreover, television programs have provided children with insights into the world of grown-ups and boys and girls now know more about each other's intimate lives. For better or worse, television has thus reduced distances between various social categories and weakened certain hierarchical and authoritarian structures.

The capacity for simultaneity between a real event and its transmission and reception as audiovisual representation, that is, 'liveness,' is central to television's specificity as a medium and its social role. It shares a form of distribution (broadcasting) with radio, it shares subject matter also with newspapers, magazines, and books, and it shares the audiovisual form of representation with film. Early television was all 'live,' but now nearly all television programming is prerecorded. Television producers and broadcasters actively seek the impression of immediacy or 'liveness'; it is simply a key aesthetic value in television. This is related to what Barthes (1981) termed the 'photograph effect': When we see a photograph we (used to) know that what is in the picture has actually once been in front of a camera. Television wants this, and more: not just 'this really happened,' but 'this really happens, right now!' Studio debates, interviews, and variety shows will either be live or try to appear to be. Pretaped shows like sitcoms will often inform us that they are 'taped in front of a live studio audience.' Liveness is particularly important to newscasts, since 'news' as a genre is based on getting as close to immediacy as possible. This is why reporters often talk to the camera – 'live,' 'on the spot' – at a dark place where nothing is happening (anymore). What is at work here is an equation of 'live' with 'real': liveness means reality, or *truth*.

A medium that can give us 'reality in the raw,' unfolding as it happens, cannot lie, it would seem, and this ability tends to lend a particular quality of immediacy, realism, or truth to much more than live programming (cf Heath and Skirrow, 1977). 'Liveness' as an aesthetic value is, therefore, still important even if new technologies and styles of presentation progressively make the medium *less* 'live' (cf Feuer, 1983). Caldwell (1995) has argued that television is more and more becoming a medium not about outside 'events' but about itself and its visual style. But there is still much live programming, and liveness as an effect remains important for the above reasons.

'Liveness' is furthermore a key to television's ability to establish experiential communities. It strengthens the general experience of collectivity in the act of viewing (cf Rath, 1989). Televised national events manifest and support national identity, and so the question is whether or to which extent globally televised events – rock concerts, Olympic games, royal weddings, or funerals – can contribute to the establishment of a new sense of transnational community. Dayan and Katz (1992) argue that television's live broadcasts of major events function as rituals that not only reinforce existing symbolical orders but also create new ones. This is just one of the ways in which television continues to be of great political, social, and cultural importance (*see* Media Events).

Already since the mid-1990s, television as we have known it has by many been said to be about to disappear. Digitalization leads to convergence with any and all other media of communication. The distributive model of broadcasting may appear to be replaced by a structure related to that of the World Wide Web, that is, a system without designated centers, presenting unlimited choice of contents to consumers. These consumers must now be thought of as active individuals and hence the term 'audience' is no longer adequate – they also produce audiovisual content and are also otherwise productive in relation to the medium, hence terms like "prosumers" have appeared. (cf e.g., Jenkins, 2006). A number of publications have dealt with these changes and often tried to prophesize about the medium's future, e.g., Banet-Weiser, Chris and Freitas (eds.): *Cable Visions: Television Beyond Broadcasting* (2007) and Amanda Lotz' *The Television Will be Revolutionized* (2007).

It may, however, also be argued that a total revolution is envisaged mostly on the basis of technological possibilities and that the outcome of an undoubtedly comprehensive process will be modified by social and cultural forces and interests that may sustain the further existence of broadcast television. Total fragmentation and individualization will be restrained by the need for community-forming, shared media experiences, and the need for competent, reliable editorial services or guidance in the confusing mass of contents on offer. Commercial interests will no doubt seek to exploit such needs and strive to establish control of gateways to and routes within the new landscapes of electronic information and entertainment. Governments may seek to find ways of securing the production of identity and distribution of cultural resources represented by the classic broadcasting model, particularly in its public service versions. Historical experience with introductions of new media indicates that already existing media survive alongside the newcomers. Theater was not killed by film; film was not killed by television. Even radio survived television, and books and newspapers are still around.

The dynamics of the ongoing process present television research with a number of exciting, difficult tasks, even if the profession of prophets should not be confused with that of serious scholars. The situation calls for studies of the relations between technological developments, economic forces, sociocultural structures, and, not least, the space for political

interventions. Such studies could well be motivated by an interest in how democracy is served by various media systems and structures. The link between theories of democracy and media is generally in need of sustained, philosophically qualified reflection. The process of convergence and increased interactivity also calls for in-depth analyses of the uses and functions of new and old versions of television, not least the ways in which new and old forms relate to each other. Finally, digitalization opens a whole set of new aesthetic and rhetorical possibilities; new forms of representation, new ways of telling stories, new ways of persuading consumers and citizens. While all of these new areas of inquiry will no doubt require new theoretical and methodological tools, the experiences of some 65 years of television research are well worth keeping in mind. Reinventing the wheel remains a waste of time.

Abstract

In the two decades after World War II, television became the most popular mass medium throughout most of the world. The USA developed the most successful commercial model, one that relied on advertisers to sponsor programming primarily intended for large audiences. With a vast comparative advantage in film production facilities, the USA was the largest exporter of TV entertainment shows. Most other nations, after long resisting the US model, not only aired many US series but had one or more commercial networks. Despite its global influence, US television underwent several transformations between 1950 and 2000. Initially, national networks, in combination with major advertisers, dominated the medium. Viewers chose from a limited number of channels, most of which were affiliated with a network. But beginning in the 1980s, cable and other new technologies began to undermine the networks' hegemony if not the very concept of mass audiences for TV programming.

Forecast in novels and science journals since the late nineteenth century, television came to the USA and other developed nations in the decade and a half following World War II. Major manufacturers of radio receivers, led by Radio Corporation of America (RCA), as well as individual entrepreneurs had labored in the 1930s in the USA, Germany, and the UK to perfect a device capable of receiving over the air clear images and sound. US companies had been especially anxious to perfect a receiver that could be mass produced. Military research during World War II had advanced their work.

In the late 1940s, the USA was best positioned to experience a 'television boom.' RCA and other companies were offering television sets that, though expensive, were not beyond the means of most consumers. At the same time, RCA established a nationwide network, National Broadcasting Company (NBC), that offered set owners regular programming. Another TV set manufacturer, Du Mont, similarly founded a TV network, as did the radio networks, ABC and Columbia Broadcasting System (CBS) (Du Mont ceased operations in 1955). The four chains provided programming to individual stations, most of which, because of federal regulations, were not owned by the networks. With TV stations operating in most of the nation's larger cities, consumers began purchasing sets. A strong economy allowed such consumption. So did the postwar boom in marriages and child-bearing, which left many young adults housebound, thus making television relatively cost-efficient home entertainment. Although high income was a strong predictor of set ownership in the first years of the television boom, family size soon became the stronger variable. By the late 1950s just under 90% of all US homes had one or more televisions. In time, owning a television became an expectation throughout the world. That said, television spread more slowly in poor countries because of the relatively high costs of receivers, the absence of electrical service and uneven TV production standards.

In contrast to what emerged in many other nations, the so-called 'American' system followed the US radio model of privately owned broadcast stations and networks carrying programs or series paid for and sometimes produced by advertisers. Oversight by the US Federal Communications Commission (FCC) was nominal. As the medium's patron, advertisers held enormous control over programs in television's first dozen years, especially because demand favored them over networks and stations. They normally sponsored entire shows, often including plugs of their wares. In most instances, advertisers sought the largest possible audience. This came to mean relying on a set of program 'genres,' most of which owed something to radio and motion pictures. That said, a few sponsors self-consciously cultivated a smaller, elite audience by underwriting musical, dramatic, or news programs. Many advertisers and broadcasters initially assumed that the TV viewer was better educated and well to do. Partly because of this misidentification of the audience, which also occurred during the early years of radio, many network programs were culturally ambitious. Original dramas, produced in New York, the nation's theatrical center, appeared every night. Critics later insisted that the USA had experienced a 'Golden Age of Television.' However, the fare most identified with the Golden Age could not, over time, compete for viewer favor with other, less pretentious efforts.

In the late 1950s, US television underwent a series of changes that established industry practice for the remainder of the century. As television spread into smaller communities, demand for dramatic and comedy programs that had followings in the larger cities collapsed. Individual comics like Milton Berle and Sid Caesar, whose humor resonated with eastern viewers, were unable to sustain their early success. The larger, more representative audience preferred filmed programs, including westerns and detective dramas, that were inexpensive imitations of motion pictures. This shift in demand encouraged the movement, already underway, of TV production from New York to California. Television increasingly took on the look of Hollywood as opposed to Broadway. At the same time, a sharp increase in advertiser demand gave the networks and larger stations the upper hand over advertisers in programming decisions. By the mid-1960s, most television programs had multiple sponsors.

Outside of Latin America and the Caribbean, much of the world actively sought to avoid taking up the US system. Much as they had disdained US motion pictures, political and intellectual elites abhorred what they construed to be the vulgarity of US television. As a result, few broadcasters enjoyed the autonomy of their US counterparts. Communist and many third-world countries tightly controlled television's development and production. The Soviet Union and other regimes regarded television, like radio, as state instruments. Other

countries, notably in Western Europe, followed the corporation model of the British Broadcasting Corporation (BBC). Under the British model, the government created an independent broadcasting authority that relied on receiver fees rather than advertising. In the mid-1980s, about two-thirds of Europe's television authorities derived their revenues from receiver fees, as did about half of all African and Asian systems. Most of the time, BBC was free of direct government interference. The UK did permit commercial television in creating the Independent Broadcasting Authority (IBA) in 1955. But commercial TV in the UK, as in many other nations, was subject to far more regulations than in the USA. In the UK, non-government TV endured an excess profits tax that had the effect of encouraging more elaborate cultural programming that rivaled the self-conscious, educational efforts of BBC. The Japanese Broadcasting System (NHK), in contrast, gave commercial TV far greater freedom. Although former British colonies initially embraced the BBC model, political anxieties caused the leaders of most newly independent countries to take up more direct, state control akin to that of the Soviet Union. Then, too, the relatively high cost of starting television service and the absence of domestic commercial investors partly explained the adoption of the statist model in most poor nations. Some third-world leaders sought to put off TV's development indefinitely, only to relent under pressure from urban elites who had encountered television in the West.

Although many if not most nations sought to avoid the US system, few could resist its programming. In the early 1980s, UNESCO reported that most nations, including those with totalitarian or Islamic fundamentalist regimes, offered more entertainment programming than any other type. This tendency created an enormous opportunity for US producers. US-made entertainment series, especially those that emphasized action or broad humor, proved immensely popular. As in the case of motion picture assembly, US television producers had a huge comparative advantage in the emerging global market for programming. The switch of US networks to filmed series created a substantial inventory of exportable entertainment. The USA possessed unequaled production facilities in southern California, as well as the movie industry's large reserve of on-camera and production talent. A large domestic audience and advertising demand, as well as the sale of syndication rights as 'reruns' to individual US stations (and eventually, cable outlets), meant that successful US programs were profitable before they were distributed overseas. They could thus be offered relatively inexpensively. British television production, with somewhat similar advantages, was a distant second as an exporter of TV programming. Most other nations simply could not produce programming of the same standard and appeal. This was especially true in less developed countries where, Elihu Katz and George Wedell estimated in the mid-1970s, imported series constituted just over half of all programming. Indeed, viewers in some countries, Katz and Wedell noted, frequently could select from different US programs aired by competing channels at the same time. One scholar of international communication concluded in 1988, 'A kind of sameness fills TV screens just about everywhere.' Revealingly, a 1999 NATO air strike against a communications center in Belgrade, Yugoslavia, destroyed 123 episodes of three US series.

The Americanization of television throughout much of the world had its critics. One of the first, Herbert I. Schiller, regarded the US's export of programming as part of a conscious attempt by the nation's political and business elites to extend the USA's influence via communication. 'The "have-not" nations,' he wrote, 'stand practically defenseless before a rampaging Western commercialism.' More likely, Katz and Wedell argue, market forces and the law of comparative advantage, and not sinister calculation, accounted for the US's impact on television globally.

In its first decade and a half, US commercial television presented relatively little news programming, very little of which elicited controversy. News programs lost money and drew few viewers. The networks considered informational programming a way of placating influential political and cultural leaders as well as of meeting the FCC's modest public service standard. In receiving TV frequencies or licenses for a fixed term, stations promised to devote a minority of its overall schedule to programs, including news, 'in the public interest.' In theory, license renewal hinged on stations meeting this 'minority interest' standard. In practice, the FCC very rarely scrutinized individual licensees' public service schedule. Nonetheless, station managers were not prepared to ignore the agency altogether. Not surprisingly, television news tended to be uncritical of those in power and, as Nancy Bernhard has argued, supportive of America's Cold War with the Soviet Union.

By the 1960s, US networks and many stations were profiting from certain types of informational programs, specifically early evening newscasts. These were not as popular as some contemporary observers assumed. In the late 1960s, one survey indicated, just over half of all US citizens watched no network evening newscasts during a 2-week period. Yet television news did command the attention of many influential US citizens, who assumed its primacy; TV newscasts also drew increasing advertiser interest. Indeed, nightly newscasts became stations' largest single source of revenue. In the 1970s, the network evening 'magazine,' CBS's *Sixty Minutes*, with its mix of exposes and features, started winning viewers For the first time, a network news program actually competed against evening entertainment shows in popularity rankings. Imitations on other networks followed. Although none could generate the following of *60 Minutes*, because they were less costly than entertainment series, the networks earned more money carrying such programs. All told, the realization that news shows could, in fact, be even more profitable, caused broadcasters to seek more viewers by adopting a less serious news agenda. The line separating news and entertainment blurred.

The first great test of US television news came with the US intervention in the Vietnam war. The medium earned at best a low pass. Popular mythology, perpetuated by surviving correspondents (and their critics), insists that TV brought the war's horrors home every evening to a people glued to their sets. Television reporters, according to this wisdom, criticized the conflict itself and thus helped to end US involvement. Subsequent scholarship by Daniel Hallin and others has largely discredited this self-serving history. As already noted, newscast audiences were never as vast as some imagined. Nor did TV news, for a variety of reasons, show much combat footage. Relatively few reports were carried live. And in the initial years of the US build-up, 1964–66, reporters and news anchors

(or readers) passively if not enthusiastically relayed the positions of the US military and civilian leadership. After 1966, some TV correspondents did challenge, ever so mildly, the progress of the war. Yet television was hardly, as some later asserted, leading public opinion or the news media generally. Other news organizations, specifically the hugely influential *New York Times*, had already started to express skepticism about the Vietnam commitment. And television news failed, Todd Gitlin has contended, to take the budding anti-war movement seriously.

As the USA withdrew forces from Southeast Asia, network television had to cover an even larger crisis. These involved criminal activities associated with the June 1972 break-in of the Watergate apartment complex in Washington DC, by figures tied to the reelection campaign of President Richard M. Nixon. The TV networks, especially CBS, covered the Watergate story. Still, they did not do so with nearly the rapidity and thoroughness of some newspapers. Herbert J. Gans' study of the evening network newscast production in the 1970s stressed the extent to which NBC and CBS depended on the *New York Times* for their news agenda.

US television remained primarily an entertainment medium, and TV's staple product began to change. A 1970 FCC regulation restricted the networks' ownership of entertainment programming. This gave producers more freedom, and some sought to convey the more relaxed cultural climate. To many critics, this shift fostered a second 'golden age.' Shows like *All in the Family* and *The Mary Tyler Moore Show*, in violation of industry practice, dealt with contemporary issues like race relations and the sexual revolution. Dramatic series in the 1980s and 1990s, usually involving law enforcement or medicine, similarly took a more realistic tone.

Despite renewed critical respect for some shows, network television's hold over the US viewer slipped in the latter decades of the century. In the 1950s and 1960s, most US citizens received their TV service over the air. The finite size of the radio band limited the number of on-air stations the typical set could receive. And until the late 1970s, the three networks in effect determined what US citizens watched. Most TV stations remained affiliated with a network. On a given evening, nine out of every ten televisions were tuned to a network program. In the 1980s, however, the networks began losing some of their audience. Although the presence of more independent stations cut into the networks' share, the spread of cable proved the far more decisive blow. By subscribing to a cable service, consumers could greatly augment their choices, originally from four to 12 to 30 or more channels. By 1997, the average US cable system provided 47 channels. This much larger array of choices proved too tempting for most consumers. The percentage of homes with cable rose from 7.6% in 1970 to 49.4% in 1988. By the late 1990s, up to 70% of all households had cable. Others had satellite signal receivers that afforded them even more services; such systems were more common elsewhere in the world. The US network audience shrank to about half of the total evening audience.

Cable's rise had several significant effects on the television. Providing many more channels greatly weakened an original justification – scarcity of service – for broadcast regulation, as did a larger disillusionment with the efficacy of business oversight. The FCC relaxed most rules regarding public affairs programming and eventually, network ownership of entertainment programs. The growth of all-news cable channels – along with the end of the Cold War – caused the network news divisions to reduce their coverage of more serious political and international news in favor of stories more likely to attract viewers. At the same, competition from cable channels caused the established networks to forsake their traditional observance of US prudishness. Trying to hold viewers, some network program producers took more risks in their handling of sexuality and crude language. Compared with their predecessors, broadcasters worried less about offending some viewers, who could always turn to a cable channel rerunning an innocuous 1960s situation comedy. In planning a racy police drama, *NYPD Blue*, producer Steven Bochco recalled being told by an ABC official in the early 1990s 'to come up with something that would at least begin to compete with cable.'

Cable channels offered a range of programs and formats. Even so, one of the ironies of cable's growth was that the most popular cable channels relied excessively on reruns of series originally telecast on the networks. These were accompanied on some channels by professional wrestling and variety shows that targeted young men who delighted in bad taste. Many cable channels practiced 'narrow-casting,' that is, they presented programming intended to engage only sports fans (ESPN) or pre-adolescents (MTV). Although the popularity of no one cable channel could compete with any of the networks, combined the cable outlets constituted a regiment of Lilliputians tying down the three Gullivers.

The networks were also wounded by the entry of new rivals in the 1980s and 1990s. None proved more successful than Fox, whose programs usually ignored industry practice and middle class proprieties. 'We were free from the hereditary constraints at the other networks, the decades of doing things a traditional way,' a Fox vice president explained in 1997. Along with still more networks, WB and United Paramount Network (UPN), Fox frequently violated another industry rule by playing to subgroups of the national audience, that is, younger or African – American viewers.

Although the advent of more TV channels mainly on cable complicated their routines, advertisers in many ways benefited from the more competitive television. Promoters of products more appealing to a specific subgroup, like adolescents or women, welcomed the efficiencies of cable narrow-casting. At the same time, cable's growth restored some power to advertisers in their dealings with the networks. Because younger viewers were thought to be more likely to try new brands and services, product makers in the 1990s were prepared to pay more – sometimes significantly more – to co-sponsor a TV program with the 'right' demographics. That is, they began basing more of their 'media buys' on who rather than how many watched a given show. All in all, this represented an unprecedented shift by the networks' underwriters, most of whom had heretofore prized the size rather than the composition of the audience.

Amid such industry upheaval came dramatic changes in industry proprietorship. After several generations of stable ownership, all three established networks changed hands in the 1980s. Capital Cities, owners of TV stations and newspapers, purchased ABC in 1985 and then sold the network to the Disney entertainment conglomerate in 1995. In 1986, General

Electric took over RCA and NBC; investor Laurence Tisch bought CBS. Westinghouse, an electronics company, secured CBS in 1995 only to allow itself to be combined with Viacom, another entertainment concern, in 2000. Meanwhile, individual stations, some of which had been controlled by the same company or family for several generations, were sold and resold through the 1980s and 1990s. Such franchise transfers increased all the more when Congress passed the Telecommunications Act of 1996, which lifted or weakened FCC regulations, including restrictions on the number of stations individual companies could own.

With only with a few exceptions did US television remain the mass medium that it had been in 1960 or 1975. Annual rituals like the National Football League's Super Bowl commanded huge audiences, as did momentarily popular shows like *Who Wants to Be a Millionaire* and *Survivor*. Otherwise, even top-ranked network programs like NBC's comedy *Seinfeld* had to settle for a much smaller percentage of the total television audience than had comparably ranked shows a generation earlier. The future offered more of the same. The spread of the Internet into more US homes at the century's end portended ever more individualized media services.

The Historiography of Television

The history of television has only begun to command serious scholarship. Until the 1990s, most research on the medium has consisted of highly specialized studies conducted by social scientists testing theories of media influence. The first wave of this research is ably summarized in Leo Bogart's *Age of Television* (1972). Historians, except for those tied to programs focusing on the film or journalism, have all but avoided the medium, despite its immense popularity and seeming influence. Their reluctance is understandable. Few are familiar with the constantly ballooning research on media effects. Moreover, evaluating mass culture itself, as opposed to its influence, has always been a tricky endeavor, much simpler for newspaper columnists than academics. It became all but impossible in the latter decades of the twentieth centuries, as scholars in the humanities and sociology dismissed cultural hierarchies altogether as hopelessly subjective, if not indicators of class and educational attainment. Historians who could pass these obstacles faced more logistical roadblocks. In the USA, corporations have been the major players in the medium's history, and relatively few have opened their records to scholars. Then, too, the sheer volume of TV programming over the years has all but compelled historians to limit their inquiries to case studies (see, e.g., Balio 1990, Spigel and Curtin 1997). Relying on middle-class sources, Lynn Spigel has sensitively examined how US citizens sought to adapt themselves and their families to television. There have been more ambitious histories, notably by Asa Briggs (1961–95) of the BBC and Erik Barnouw's more episodic treatment of US broadcasting (1970). Paul Rutherford has written a very competent history of Canadian television (1990, see also Levy 1999).

Meanwhile, many gaps will need to be closed, including far more examinations of ethnicity and gender. Virtually no systematic investigations have been conducted on advertisers' complex and changing relationships to the medium. Much more research needs to be attempted measuring the relationships between TV news and those in power.

Finally, the tendency of program producers to take up concepts first developed overseas needs to be explored. Successful US series had many imitators over the years. Still, the phenomenal success at the end of the twentieth century of ABC's *Who Wants to be a Millionaire* and CBS's *Survivor*, both modeled after European programs, demonstrated that even US program producers have occasionally engaged in plagiarism. CBS modeled its long-running *Sixty Minutes* after a Canadian program. British programs inspired such popular US series as *All in the Family* and *Sanford and Son* as well as some far less resilient endeavors.

Temperament

Samuel P Putnam, Bowdoin College, Brunswick, ME, USA

Abstract

Temperament represents the earliest manifestations of, and basic foundations for, the developing personality and thus is an essential starting point for the understanding of individual differences in humans and other animals. Coherent patterns of behavior are apparent early in life, are rooted in individuals' biological characteristics, and demonstrate consistency over time and situation, organizing the characteristic ways individuals respond to the environments they encounter. These early tendencies develop with maturation and in response to experience, contributing to adaptive and detrimental outcomes throughout the life course.

Definition

Although theorists differ on the specific boundaries of the concept, a degree of consensus has been achieved regarding defining features of temperament (Shiner et al., 2012). Temperament traits are relatively stable, constitutionally based individual differences in activity, reactivity, and regulation that emerge early in life and are shaped by complex interactions between genetic, environmental, and maturational factors. Stability of temperament may be modest in early years due to maturational processes that alter the ways in which underlying processes are manifest in behavior, and increases substantially at later ages. The term 'constitutional' refers to the biological bases of temperament traits, including activity at the genetic, epigenetic, neural, and physiological levels. Reactivity concerns differences in individuals' characteristic behavioral, attentional, and biological responses to change in the environment. Regulation refers to processes that act as modulators of reactivity, including effortful control of behavior and attention, as well as tendencies to approach or withdraw from stimuli (Rothbart and Derryberry, 1981).

Temperament is viewed as a subset of personality characteristics. Although the two constructs share an emphasis on the endurance of individual differences over time, personality is a wider term that encompasses goals, opinions, ideas, and conceptions of the self; cognitively based attributes that are not typically considered aspects of temperament. This focus on overt behaviors allows temperament to be studied in nonhuman animals and infants, allowing for important insight regarding the neurological and developmental origins of temperament, and recently proposed criteria for temperament includes counterparts in primates and other social animals (Zentner and Bates, 2008).

History

Concepts of temperament are apparent in ancient philosophical perspectives. Rothbart (2011) has drawn similarities between modern approaches to individual differences and Indian Rig Vedas and Chinese notions regarding chi. In Western tradition, Greco-Roman physicians, most notably Galen and Vindician, related aspects of behavior with individuals' physical constitution. The term 'temperament' is derived from the Latin 'temperamentum,' referring to proportional mixture, and the Greco-Roman model viewed temperament as being determined by the relative levels of different bodily fluids, resulting in four main types of persons. The melancholic person was believed to have an excess of black bile, predisposing them to negative moods such as fear and sadness. A predominance of yellow bile was associated with the choleric type, who were highly active, ambitious, and quick to anger. The sanguine individual was a friendly and outgoing pleasure seeker with excess levels of blood; and the phlegmatic person was calm and controlled, their even-tempered nature attributed to a predominance of phlegm. This model endured through the Middle Ages and Renaissance, and references to this typology can be found in the writings of Kant in the eighteenth century.

Pavlov's research on classical conditioning is a foundational pillar to the understanding of nurture in shaping behavior, but Pavlov's appreciation of the importance of nature is less well-known by Western scholars. In conducting his studies regarding conditioning of canines, Pavlov and his colleagues became aware of substantial and consistent differences in the responses of individual dogs to experimental paradigms, proposing differences in threshold for inhibitory and excitatory brain processes as underlying factors, and relating these differences to the ancient typology. For instance, sanguine dogs were those who were adaptive to changes in situation, easily acquiring conditioned responses, whereas melancholic animals demonstrated distress when encountering difficult discrimination tasks, sometimes losing conditioned responses they had previously acquired.

Early Western approaches to individual differences focused on questionnaire responses, and used the statistical technique of factor analysis, which empirically groups large numbers of variables to discern a smaller number of broad factors. The earliest effort in this vein was conducted in 1906 by Heymans and Wiersma. Using ratings made by doctors regarding their adult and child patients, three factors were identified: Activity (degree of energy expended in response to goals or stimuli), Emotivity (tendency to emotional reactions such as fear), and Primary–Secondary Function (tendencies to react impulsively rather than in a more slow and organized fashion). Subsequent factor analytic studies in Britain by Webb and Burt, and in the US by Cattell, revealed dimensions including introversion–extraversion, neuroticism, and will, establishing a tradition

linked to the Big Five or five-factor models commonly used in contemporary personality research.

Normative studies of infant and child development also contributed strongly to contemporary research on temperament. Gesell, through observations of large numbers of children, and Shirley, who intensively investigated small samples, aimed to establish timetables for normal sequences of motor and mental capabilities. In doing so, they became aware of notable variability in the children they studied. These researchers found these differences to be consistent across situation and proposed that the patterns of behavior formed the bases for emerging personality. A follow-up investigation of the infants studied by Shirley when they were adolescents provided support for this notion, as independent descriptions of the teens' personalities were predicted by sketches of their behavior during infancy (Neilon, 1948). These authors elucidated a number of principles regarding individual differences that foreshadowed current work on temperament, proposing that early appearance and consistency of traits, as well as similarity in traits among family members, strongly suggested genetic origins of personality.

The prominence of social learning theories emphasizing reward and punishment in the middle decades of the twentieth century resulted in a relative deficit of research on temperament. Notable exceptions from this period include Bergman and Escalona, who identified differences among children in their sensitivity to low levels of stimulation; Fries and Woolf, who documented differences in neonatal activity level; and Kagan and Moss, who demonstrated consistency of shy and timid behavior from age three through young adulthood (see Rothbart, 2011). Inspired by her findings, Escalona (1968) proposed the concept of 'effective experience,' suggesting that the unique ways that children's nervous systems respond to stimuli can cause identical environments to have very different meanings for different children.

Many temperament scholars would agree that the modern era of temperament research began with the publication of the initial report of their New York Longitudinal Study by Alexander Thomas, Stella Chess, and their colleagues (Thomas et al., 1963). Thomas and Chess were clinicians who noted substantial numbers of children who were experiencing adjustment difficulties despite the apparent absence of environmental challenge, as well as children who seemed to thrive in troubling circumstances, and argued that children differed from the earliest days of life, with these differences predisposing them to a wide range of adaptive and maladaptive outcomes. They initiated a study of infants between the ages of 3 and 6 months, interviewing their parents extensively regarding their children's responses in a variety of situations to quantify what they termed 'primary reaction patterns,' only adopting the term 'temperament' in their later publications. Thomas and Chess followed a sample of over 100 children through early adulthood, publishing their findings in multiple books that continue to influence clinicians, interventionists, parents, and researchers today.

Structure

An important beginning point for understanding temperament concerns identification of the underlying pattern of early individual differences. In addition to allowing for increased parsimony, identification of these basic elements of temperament may be useful in generating information regarding biological factors, as related behaviors may be controlled by common neural and physiological processes. An early organizational rubric was created by Thomas and Chess, who sorted parents' descriptions of their children on conceptual bases, resulting in nine behavioral dimensions: (1) Mood, (2) Approach versus Withdrawal, (3) Adaptability, (4) Intensity, (5) Rhythmicity, (6) Activity Level, (7) Threshold, (8) Distractibility, and (9) Attention Span/Persistence. Concerns, however, have been raised regarding this model. Some of the Thomas and Chess dimensions, such as Distractibility and Attention Span, overlap substantially. Conversely, analyses of scales measuring other dimensions suggested the existence of more than one factor. For instance, items in Mood scales assessing positive emotionality often did not correlate highly with those measuring negative affect.

Rothbart and colleagues have developed a battery of questionnaires that incorporate a revised set of constructs from the Thomas and Chess dimensions with those from other models of child temperament, adult personality, and animal research. Separate instruments designed for infants, toddlers, older children, adolescents, and adults contain upto 20 scales each. Factor analyses of these instruments suggest a common structure involving three broad dimensions across the lifespan (Putnam et al., 2001). A factor referred to as Surgency/Extraversion includes scales measuring activity level, approach, and impulsivity, as well as expressions of positive affect, especially during intense activities. A Negative Affectivity factor involves high levels of, and difficulties recovering from, frustration, sadness, and discomfort; fear is also associated primarily with this factor, but not as strongly as the others, and is also associated with low levels of Surgency. A third factor, labeled Orienting/Regulatory Capacity in infancy and Effortful Control thereafter, consistently contains scales measuring tendencies to focus attention. At younger ages, this characteristic is complemented by enjoyment of calm activities and close contact with others; at older ages, the ability to demonstrate inhibitory control and perform necessary but unpleasant tasks joins attentional control in defining this factor. These factors have been replicated in other cultures and are similar to those that have emerged from factor analyses of observational data gathered in the laboratory and from other measures of temperament and personality, as well as those identified among nonhuman animals, suggesting evolutionary origins of the biological systems implicated in these broad patterns of behavior (Rothbart and Bates, 2006).

An alternative perspective on the organization of temperament involves discernment of temperament types, often done through identification of common combinations of dimensions. In an early example of this 'person-centered' approach, Thomas and Chess (1977) proposed a categorical system, in which children could be characterized as 'difficult' (negative mood, withdrawing, unadaptable, intense, and irregular), 'easy' (positive mood, approachful, adaptive to change, low in intensity, and regular), or 'slow to warm up' (withdrawing, low activity level, low intensity). More recently, a number of researchers have identified a related scheme, in which children and adults can be classified as 'undercontrolled' (quick to

anger, disruptive, impulsive), 'overcontrolled' (shy, low activity level, compliant), and 'resilient' (positive, confident, emotionally stable). Zentner and Shiner (2012) have discussed the relative merits of the typological and dimensional approaches, concluding that both offer unique benefits to the understanding of individual differences.

Measurement

Although self-report questionnaires have been developed for older children and adults, teachers occasionally provide ratings of children, and temperament has been assessed in naturally occurring settings, the large majority of studies have measured temperament via questionnaires completed by parents or observations of children's responses to structured tasks. Questionnaires are advantageous in terms of both their depth and breadth. Parents see their children over long periods of time, so that general patterns of response can be reported upon, and observe their offspring in a wide variety of situations, including those that are logistically and ethically difficult to recreate in the lab setting, allowing for assessment of a large number of dimensions. Questionnaires are also relatively easy and inexpensive to administer, easing demands on participants, and enabling collection of large samples. Parent reports, however, have been criticized over concerns regarding parental bias, inaccurate recall, limited comparison bases, and other factors that may lead to inaccuracy. Structured observations are advantageous, in that they allow researchers to carefully control situations and objectively code specific behaviors. These situations, however, are often brief and somewhat artificial, and the laboratory situation itself may be stressful, influencing child behavior in ways that obscure their typical responses.

Acknowledging the pros and cons of differing measurement techniques, contemporary scholars have adopted a 'components-of-variance' interpretation, viewing parent reports as involving both subjective and objective components (Rothbart and Bates, 2006). Similarly, observational measurements will yield scores influenced by both the child's general tendencies and behavior unique to the specific situation and moment. Lending support to this view, convergence across methods has been demonstrated frequently, but not always (see Putnam et al., in press, for a recent review). Multimethod approaches are recommended whenever possible, but single method studies are still valuable when interpreted in light of their limitations. By comparing and contrasting findings generated with differing measures, a richer perspective can be gained regarding the phenomenon under consideration.

Biological Bases

Emphasis on constitutional origins is common to all definitions of temperament, and knowledge in this area has accelerated in recent years in correspondence with advances in methodological sophistication. A fundamental change concerns the presumed role of genes. Whereas early views conceptualized temperament as largely genetically determined at birth, with increasing influence of the environment over the lifespan, contemporary perspectives acknowledge the dynamic interplay of biological and environmental factors from the moment of conception (Shiner et al., 2012). It is now clear that pre- and postnatal influences alter the expression of genes, that some genetic influences do not emerge until later in development, and that genes are implicated in change, as well as stability, of behavioral patterns.

The findings of quantitative genetics research, which compares the behaviors of individuals differing in the similarity of their genetic profiles (e.g., monozygotic and dizygotic twins), are consistent with the suggestion that approximately 20–60% of variability in temperament traits is due to genetic differences (Saudino and Wang, 2012). In contrast to the intuitive expectation that the role of genes might be more profound at early ages, most studies suggest increases in genetic effects across the lifespan, as individuals select and elicit environments consistent with their genetic makeup. Longitudinal studies with genetically sensitive designs suggest an additional possibility that temperamental characteristics may be influenced by different genes at different times (e.g., before and after puberty).

Enthusiasm regarding molecular genetic studies, in which differing forms of individual genes are associated with temperament dimensions, has waned somewhat, due to inconsistencies in findings and frequent failures of replication studies. Despite the number of conflicting results in this burgeoning area of research, some general patterns are apparent (Saudino and Wang, 2012). Allelic variation in genes linked to dopamine systems has been connected in several studies to surgent and regulatory aspects of temperament, whereas genes associated with serotonin have been most frequently related to individual differences in temperament dimensions involving sociability and affect.

Genetic activity is translated to individual differences in behavior through processes involving the central and peripheral nervous systems. Research into the neural bases of temperament has frequently considered individual differences in the reactivity of neural systems implicated in emotional responses. The most influential studies in this area have been those conducted by Kagan (e.g., 1994) on children who are extreme in behavioral inhibition, demonstrating high levels of hesitance and negative affect in the face of novelty, in comparison to children who are relatively fearless. Relative to uninhibited children, inhibited children tend to exhibit high and stable heart rates, muscle tension, and high levels of norepinephrine; and react to stressful situations with exaggerated cardiac acceleration, pupil dilation, and elevated levels of cortisol. Kagan has argued that this profile is largely due to low thresholds for arousal in sections of the amygdala, and a follow-up study of adults that had been inhibited or uninhibited as young children have indeed revealed greater fMRI signal response in the amygdala in the former when viewing novel, in comparison to familiar, faces (Schwartz et al., 2003).

Regarding regulatory functioning, frontal neural networks, most notably the anterior cingulate cortex (ACC) and lateral prefrontal cortex play central roles (Posner and Rothbart, 2000), and correlations between anatomical aspects of the ACC and self-reported Effortful Control have been documented (Whittle et al., 2008). Regulatory aspects of temperament have also been related to peripheral measures. Variability in heart rate that occurs in response to respiration provides

an estimate of parasympathetic nervous system function, providing a route for regulation of emotional processes. Both high degrees of variability and large reductions in variability during situations requiring constraint have been associated with enhanced attentional and emotional regulation.

Development

Although several studies have now demonstrated consistency of individual differences from early childhood through adulthood (see Zentner and Shiner, 2012), this consistency is relatively modest and a developmental perspective requires the acknowledgment of change as well. Neural and motor systems underlying temperament undergo immense maturation during infancy and childhood, with regulatory processes increasingly laying influence upon more purely reactive systems (Rothbart and Derryberry, 1981). One important shift occurs in the second half of the first year of life, as fear-based inhibition emerges, functioning as a 'brake' on the 'accelerator' of more early developing approach tendencies. Across early childhood, this system is complemented by increases in more effortful regulation of attention and behavior. These later-developing characteristics not only represent traits that can only be assessed after the infancy period; they also allow for more flexible and intentional demonstration of other traits, leading to a degree of instability in these dimensions. Maturation of these capabilities continues after toddlerhood, but occurs at a slower pace. Correspondingly, estimates of stability increase sharply after the age of three, but do not reach a peak until late adulthood (Roberts and DelVecchio, 2000).

To take into account maturation, in addition to changes across development in the social acceptability of affective displays, researchers often consider heterotypic continuity. In contrast to homotypic continuity, which refers to consistency in identical or similar behaviors over time, heterotypic continuity involves connections between behaviors that may differ dramatically in form, but share a common biological or functional origin. For instance, Kagan (1994) found that infants who demonstrated a high motor activity and crying to novel stimuli at 4 months showed restricted activity in their failure to approach an unfamiliar adult when asked to do so as toddlers and were more serious than their peers when interviewed as adolescents. Heterotypic continuity has also been invoked to explain the influence of one trait on the developmental pathway of another, and the direction of influence may change with age. For example, high surgency in infancy has been shown to predict higher levels of effortful control in toddlerhood, but this pattern is later reversed, with high toddler surgency associated with decreased effortful control in older children (Putnam et al., 2008).

Context and Outcomes

The increase in volume of research on temperament in recent decades has been matched by breadth of investigation, and temperament has been integrated with an immense array of other constructs. Due to the correlational nature of much of this research, the causal direction of these relationships is frequently obscure. This is most apparent in studies of the proximal environment. The actions of parents and other persons are presumed to shape children's developmental trajectories, but children also shape the actions of those with whom they interact. Processes of dynamic reciprocity also take place between distinct aspects of the individuals themselves. That is, although phenomena such as adjustment or physical health are usually conceptualized as outcomes of temperament, the reverse is also plausible in many cases. Direction of causality is less ambiguous for certain types of variables. Biological sex and cultural forces are not open to influence from the behavior of individual children. Research on these overarching contexts is covered below, followed by description of research linking temperament with parenting and adjustment, before attention is turned to efforts to apply understanding of temperament to benefit individuals and their families.

Sex and Culture

Although reverse causality is logically improbable, the degree to which cross-cultural or sex differences in temperament are due to genetic or socialization factors is uncertain. Quantitative genetic designs are suited to discerning differences within populations, not between groups, so shed little light on this issue. The fact that some differences have been identified in early infancy suggests that the organizing role of the X/Y chromosomes and population-wide differences in the frequencies of alleles may explain a portion of the variance; alternately, the fact that many sex and cross-cultural differences emerge, increase, or decrease across childhood and adolescence suggests that environments shape these individual differences as well.

A recent meta-analysis of 191 studies by Else-Quest et al. (2006) revealed sex differences in several temperament traits. The largest effects were found among dimensions associated with surgency and effortful control, with males demonstrating higher activity level, impulsivity, and enjoyment of high-intensity stimuli; and females exhibiting a higher degree of inhibitory and attentional control. Girls also tended to express greater positive affect during low-intensity situations and were more sensitive to subtle changes in the environment. Fewer differences were found in aspects of negative affectivity. Whereas males were somewhat more likely to be rated as 'difficult,' girls expressed greater physical discomfort, fear, and sadness, with these differences becoming more pronounced during adolescence. Gender has also been investigated as a moderator of temperament effects. For instance, shyness appears to be more predictive of social difficulties in males than females, possibly due to social norms conferring greater acceptance of timidity for girls in North American cultures.

In general, shyness and social withdrawal are viewed more negatively in individualistic Western cultures than in group-oriented cultures, in which self-regulation is more strongly emphasized (Chen et al., 2012). These values are manifest in the behaviors of social partners, as Chinese parents and peers show more warmth and acceptance toward inhibited than uninhibited children, with the opposite pattern apparent among Canadian parents and youth. Correspondingly, several studies have found children in some Asian cultures to be more

fearful, less expressive, and demonstrate greater behavior control than their counterparts in Canada and the US Similar processes have been documented among individualist societies. For instance, Super and colleagues (2008) found low approach to be associated with parents' ratings of general difficultness in Italian, but not US, samples, which may explain recent findings of lower shyness in Italian than US children (Cozzi et al., 2013). Culture also alters contributions of temperament traits to outcomes. For example, whereas shyness is often linked to socioemotional problems in North America, studies carried out in Indonesia, Sweden, and China have not found this. Curiously, recent studies in China suggest that shyness has begun to relate to adjustment problems in urban parts of the country that have become increasingly market-oriented in the twenty-first century (see Chen et al., 2012). As the world becomes increasingly interconnected, other cultural effects may be similarly affected.

Parenting and Adjustment

Longitudinal studies that examine change in variables after accounting for earlier levels of the attributes have suggested that parenting both affects and is affected by temperament (see Bates et al., 2012, for a recent review). Positive emotionality and regulatory aspects of temperament demonstrate reciprocal effects, with positivity and self-regulation predicting higher warmth and positive forms of control from parents, whereas punitive control or low responsivity from parents forecasts diminished growth of self-regulation in children. Results regarding child negative emotionality influencing parenting are complex, with some studies suggesting decreased warmth in response to negativity, but others suggesting increased warmth, especially toward fearful children. Child fearfulness, in contrast, may decrease over time in response to parental warmth.

Temperament has been extensively investigated in relation to behavior problems. The general pattern of these findings suggests that general negative affectivity contributes to both internalizing and externalizing problems; fearfulness is more strongly connected to internalizing problems; and externalizing tends to be more closely related to high levels of surgency and low effortful control. A handful of studies have also documented interactions among traits. The most common result is for the detrimental effects of negative affectivity to be most profound among youth who are also characterized by low levels of effortful control.

In recent years, a classic perspective regarding temperament, parenting, and adjustment has been extended conceptually and empirically. Thomas and Chess (1977) introduced the term 'goodness of fit' in proposing that a key determinant of an individual's functioning was the degree to which their temperament was congruent with the demands of their environment. A similar perspective regarding temperament × environment interactions, the differential reactivity model (Wachs, 1992), suggests that temperament predisposes certain children to be more reactive than others to aspects of the environment. In this view, some temperament characteristics, such as negative emotionality, confer a vulnerability that leads some children to be particularly affected by stressors, whereas other characteristics, such as effortful control, serve as buffers that allow children to more readily cope with adversity. More recently, a differential susceptibility model has been proposed (e.g., Bakermans-Kranenburg and van IJzendoorn, 2011), in which individual differences in reactivity cause some children to be exceptionally sensitive to both positive and negative influences.

An elegant empirical example of temperament × parenting interaction was initially identified by Kochanska (e.g., 1997). Kochanska found that the development of morality in inhibited children was hampered by use of harsh control by mothers, but discipline style had little effect on the consciences of uninhibited children. For fearless, but not fearful, children, positive mother–child interactions and secure attachment were associated with more advanced morality. A second consistent pattern of findings suggests that children high in frustration or general negativity are more likely than less negative children to exhibit adjustment problems in response to negative parenting. Similarly, high levels of negative parenting (e.g., harsh discipline) or low levels of positive parenting (e.g., warmth) may have more detrimental effects on children low in effortful control. A recent meta-analysis applied the differential susceptibility perspective to molecular genetic findings, finding children who were carriers of 'risk alleles' in dopamine-related genes were more likely to actualize both positive outcomes in response to supportive environments and maladaptive outcomes in the presence of adverse contexts (Bakermans-Kranenburg and van IJzendoorn, 2011).

Transactional interactions between temperament and parenting have also been shown through experimental research. An influential study in this vein was conducted by van den Boom (1995). Building upon studies demonstrating correlations between difficult temperament and insecure attachment, van den Boom conducted an intervention aimed at promoting responsiveness to the emotional signals of difficult infants. In response to increased maternal sensitivity, infants in the experimental group were more likely to be securely attached and cooperative with mothers as toddlers than those in the control group. Furthermore, these children engaged in more responsive interaction with their fathers and were more frequently sought out by peers as play partners. In replications of this work, the effectiveness of interventions has been pronounced for infants who were highest on negative reactivity, but negligible for less irritable children.

Applications

Despite near-universal acceptance of temperament as an influence on development, progress has been slow in translating current knowledge regarding early appearing individual differences to practices designed to improve the human condition. Interventions incorporating temperament are often grounded in the goodness of fit framework, providing information on temperament and helpful strategies that encourage environments that are adaptive to the unique needs of individual children. A complementary goal is to alter child behavior, both by assisting children to use regulation techniques that are specific to problematic reactive tendencies and by enhancing more general capacities associated with effortful

control. Such programs can be designed and implemented at a variety of levels or tiers (McClowry and Collins, 2012), ranging from broad interventions that are aimed at fostering adaptive development of all children in a school or other setting; to more intensive efforts with children demonstrating risk for maladjustment; to strongly focused treatment for children with more advanced indication of behavior disorders.

The INSIGHTS program (see McClowry and Collins, 2012) provides a valuable model of a broad-based intervention. Over a 10-week period, the program proceeds through three steps during which parents and teachers are (1) taught to recognize, reframe, and consider their responses to children's temperament-relevant behaviors, (2) given strategies to elicit compliance that are matched to different traits, and (3) offered guidance on training children to use techniques that allow them to effectively self-regulate. A complementary program is administered to children in the classroom, using puppets to introduce children to the idea of temperament types and teaching coping strategies for challenges that arise for different individuals. The intervention has been shown to be effective, lowering rates of disruptive behavior and attentional difficulties in elementary school children from urban neighborhoods.

In contrast to the broad goals and audience addressed by programs such as INSIGHTS, higher-tier programs often emphasize single dimensions. One such intervention is the 'Cool Little Kids' program (e.g., Rapee et al., 2010), aimed at reducing risk for anxiety disorders among inhibited children. Parents of fearful children meet in small groups with a clinical psychologist to receive information regarding the effects of aspects of parenting such as anxiety modeling and overprotection, and intensive training in techniques such as gradual exposure to fear-eliciting situations. In comparison to a group who received no treatment, children whose parents completed the program had fewer anxiety symptoms when followed up 3 years later.

Once issues have led individuals, couples, or families to seek treatment, temperament can be a valuable tool for addressing a variety of clinical issues. Aron (2012) has articulated multiple ways in which temperament can lend a unique perspective to both therapists and their clients. A consideration of temperament can enhance assessment, enabling clinicians to interpret client behaviors in the context of the person's individual style. During the development of the therapeutic alliance, acknowledgment of a client's temperament may build trust and allow both members of the alliance to consider behaviors objectively, viewing traits in terms of their benefits as well as drawbacks. In addition, awareness of temperament can help provide realistic goals for the outcomes of therapy, so that "both therapist and client can develop a better sense of what can be changed and what cannot, and even should not, be changed" (Aron, 2012: 648).

Conclusion

Since the early 1970s, research on temperament has grown exponentially, with increases in publications on the topic dramatically surpassing growth in scholarship on similar topics such as attachment and personality (Zentner and Shiner, 2012). Empirical research has clearly supported ancient beliefs that the rich variety in the ways in which humans navigate their worlds have origins in biological processes and behavioral patterns that are apparent early in life. Given ongoing advances in technology and increased integration of temperament with other areas of the social and natural sciences, it is likely that growth in our understanding of the nature and implications of temperament will continue to accelerate.

Future advances in the field are sure to take the direction of increased complexity, with more studies of interactions across and within all levels of analysis (e.g., culture, social settings, family relationships, perceptions, behaviors, physiology, neurology, epigenetics, genetics). Across levels, the ways that culture affects temperament through parenting, the ways in which environments alter genetic activity, and the ways in which physiological reactions impact individuals' perceptions of their social partners are mere examples of the infinite questions that can be addressed. With levels, greater appreciation of fine-grained distinctions in biological, behavioral, and social processes will allow greater specificity in exploring, for instance, the ways in which certain traits alter the trajectory of others, or how neural systems react to the activity of one another.

Advances will also be salient in the applications of temperament to multiple settings. Implicitly, this is already occurring, as the majority of professionals in the teaching, counseling, medical, and related professions have received some training regarding temperament and the how it can inform their practices. In addition to enhancing this training, more explicit efforts, building from those recently developed by McClowry, Rapee and others, are needed, along with evaluations of exactly how, why, and for whom they are effective. Adaptations of interventions for use with different populations, as well as modifications to protocols that are based on efficacy studies, can combine with basic research in a circular fashion that holds promise for transformative change.

Abstract

Temperament refers to early-appearing dispositions upon which personality is based, and research on temperament offers an important place to begin in the study of human development. Rather than seeing individual differences solely as the result of socialization, temperament research identifies basic dispositions toward affect, arousal, and attention that will be further shaped by experience in development. In this article, temperament is defined, a brief history is presented, current research is reviewed, and directions for the future are outlined.

Because temperament refers to the early-appearing dispositions upon which personality is based, it can be studied in infants and nonhuman animals as well as older children and adults. It offers an important place to begin in understanding human development. Rather than seeing individual differences in personality and social behavior as solely the result of socialization, temperament research identifies basic dispositions toward affect, arousal, and attention that will be further shaped by experience in development.

A Definition of Temperament

Temperament has been defined as constitutionally based individual differences in emotional, motor, and attentional reactivity and self-regulation, demonstrating consistency across situations and relative stability over time (Shiner et al., 2013). The term 'constitutional' stresses links between temperament and biology. Over the long history of the study of temperament, individual differences in temperament have been linked to the constitution of the organism as it was understood at the time. The term 'reactivity' refers to the latency, rise time, intensity, and duration of responsiveness to stimulation. The term 'self-regulation' refers to processes that serve to modulate reactivity; these include behavioral approach, withdrawal, inhibition, and executive or effortful attention.

History of Temperament Research

Temperament study has an ancient history: individual differences in temperament were described in the fourfold typology of the Greco-Roman physician Vindician, who linked temperamental characteristics to Hippocrates' model of the humoral constitution of the body. The term 'temperament' derives from the Latin *temperamentum*, a proportionate mixture, denoting the relative preponderance of one or more of the body humors. In Vindician's typology, the melancholic person, quiet and moody, was seen as having a predominance of black bile; the choleric person, touchy, aggressive, and active, a predominance of yellow bile; the sanguine person, sociable and easygoing, a predominance of blood; and the phlegmatic person, calm and even-tempered, a predominance of phlegm. Ideas about the fourfold typology of temperament persisted throughout the Middle Ages and the Renaissance, and were found in the writings of Immanuel Kant.

Early in the twentieth century, major schools in Europe and the UK contributed to temperament research (Kagan and Fox, 2006). An Eastern European tradition began with I. P. Pavlov's observations of individual differences in his dogs' behavior in the laboratory. On the basis of the dogs' reactions, Pavlov and his followers posited characteristics of the nervous system, including strength or weakness of excitation and inhibition, and nervous system lability. This was nevertheless a conceptual nervous system; the nervous-system characteristics were based on behavioral observations. Work in Eastern Europe continued in Nebylitsyn's studies of individual differences in the laboratory, with adults as subjects. In the late twentieth century, due to a lack of consistency across stimulus modalities and response systems in the laboratory, questionnaire assays of individual differences have been undertaken.

In Central Europe, research on temperament in The Netherlands was to become highly influential. Heymans and Wiersma, in 1908, asked 3000 physicians to observe a family (parents and children) and to fill out a temperament/personality questionnaire on each person. When the more than 2500 responses were analyzed, three factors were identified: activity (the tendency to act out what is thought or desired), emotivity (the tendency to show body symptoms, to be fearful and shy), and primary versus secondary process (the tendency to react immediately or in a postponed and more organized way). This research, which involved a wide range of subjects, was followed by European research on temperament in early development, with intense longitudinal observation of infants. Wallon in France and Meili in Switzerland investigated infants' muscle tension and emotionality, and Meili reported stability across time in infants' irritable or anxious responses to standardized stimuli. Meili's contributions showed a similarity to later research in the USA on temperamental emotions and behavioral inhibition (G. Balleyguier, personal communication, 8 September 1996).

In the UK, factor-analytic studies of individual differences in temperament and personality were carried out using adults' self-reports. Early work yielded factors of introversion–extraversion,

emotional stability–instability (later called by Eysenck 'neuroticism'), and volition or will (Kagan and Fox, 2006). Eysenck added a physiological base to the temperament factors by relating them to cortical excitation and inhibition, and the functioning of the limbic system. Still later, Gray revised Eysenck's theory by positing individual differences in behavioral activation and inhibition, as well as tendencies to fight and flight. He also related these individual differences to an underlying neurophysiology. At the turn of the twenty-first century, Gray's theory was one of the major psychobiological models of temperament, along with models put forward by Panksepp et al. (2005).

In the USA, there were multiple contributions to the study of temperament. Allport used temperament in his trait-based theory of personality, and Cattell and Thurstone carried out early factor-analytic research on temperament and 'vectors of mind.' These would later be followed by research on the Big Five personality factors in adults (Biesanz et al., 2004). Nevertheless, in early research on child development, temperamental dispositions were rarely discussed. Instead, social-learning theories stressed the importance of reward and punishment in shaping behavior and accounting for individual differences. The study of cognitive development would also become much advanced before the study of emotional development and temperament became popular. Only in the late twentieth century did research grow and flourish in temperament and development. This renewed interest has been linked to the realization that the direction of parent–child influence is not only from parent to the child, but that the infant and the young child also bring much to shaping the interaction (Collins et al., 2000). Interest in temperament has also been linked to advances in neuroscience, with knowledge of individual differences in temperament providing links to genes and neural networks, as well as to social interaction.

Current Research

In the USA, the New York Longitudinal Study (NYLS) by Thomas, Chess, and colleagues formed the basis for much of the recent research on temperament in children. Parents of infants between the ages of 2 and 6 months were interviewed about their children's behavior across a wide variety of situations. A content analysis of interview information on the first 22 infants yielded nine dimensions of temperamental variability: activity level, rhythmicity, approach-withdrawal, adaptability, threshold, intensity, mood, distractibility, and attention span-persistence. The goals of the NYLS were chiefly clinical, and no attempt was made conceptually to differentiate these dimensions from one another. Nevertheless, numerous parent-report questionnaires were developed based on the nine NYLS dimensions.

As a result of more recent research, however, major revisions to the NYLS list have been proposed (Rothbart et al., 2000). Both factor-analytic research using NYLS items, and research following a more rational approach such as that of Rothbart, have identified a shorter list of temperament dimensions. These dimensions include positive affect and approach (extraversion or surgency), fearfulness, anger/frustration, attentional orienting, and executive attention (effortful control). These dimensions are particularly interesting because they are evolutionarily conserved affective-motivational and attentional systems. They serve adaptive functions, and can be seen in nonhuman animals as well as in the human species (Panksepp, 2005).

In factor-analytic studies of parent-reported temperament in childhood, three to four broad factors are frequently found (Rothbart et al., 2000). The first of these is surgency or extraversion, which includes activity level, sociability, impulsivity, and enjoyment of high-intensity pleasure. The second is negative affectivity, including fear, anger/frustration, discomfort, and sadness, and the third is effortful control, including attentional focusing and shifting, inhibitory control, perceptual sensitivity, and low-intensity pleasure.

Current research on temperament in childhood makes use of parent-report questionnaires, laboratory assessments of children's behavioral and psychophysiological responses to standardized stimuli, and observations of children's behavior in the home or school. With this information, it has been possible to study the development of temperamental systems, and to relate temperamental functioning to other important outcomes. These include the development of empathy and conscience, the development of behavior problems, children's adaptations to the classroom, their susceptibility to drug and alcohol abuse, and their accident-proneness.

Developmental research also indicates that the emotional systems of temperament and reactive attentional orienting are in place before the development of executive effortful attention (Rothbart et al., 2000). In the newborn, individual differences in irritability and orienting can be observed, and by 2 to 3 months, infants demonstrate clear positive responses to stimulation. Early forms of what will later be called extraversion or surgency are present in the smiling and laughter and rapid approach of infants, and measures of approach tendencies and smiling and laughter at this early age predict children's extraverted tendencies at 7 years. Throughout early development, children who are more extraverted also seem to be more susceptible to anger and frustration.

At 4 months, individual differences in infants' distress and body movement to stimulation predict later fear and behavioral inhibition. By 6 months, it is also possible to predict seven-year-old children's parent-reported frustration and anger by the infant's responses to toys out of reach or behind a plastic barrier. Infants' behavioral approach tendencies are also manifested at 6 months in their latency to reach and grasp objects.

The onset of fear or behavioral inhibition in the last quarter of the first year of life appears to work in opposition to the infant's approach tendencies, so that some infants who formerly rapidly approached novel objects are now slowed in their response to novel stimuli, and may not approach at all. They may also show distress to possibly threatening objects. As with approach tendencies, individual differences in fear-related behavioral inhibition show considerable stability across childhood and even into adolescence (Rothbart and Derryberry, 2002). Longitudinal research has reported stability of fearful inhibition from 2 to 8 years, and from the preschool period to age 18.

Fear-related control of behavior can be seen in the early development of conscience (Kochanska, 2002). Fearful

children are more likely to show early signs of conscience. In addition, fearful children whose mothers use gentle discipline, presumably capitalizing on the child's tendency to experience anxious states, develop highly internalized conscience. More fearful infants also later tend to be empathetic and susceptible to guilt reactions. Fear can thus be seen as a basic control mechanism that is importantly implicated in socialization.

Beyond the inhibitory control provided by fear, a later-developing attentional system makes a crucial contribution to socialization. As executive or effortful attention develops in the second or third year of life and beyond, individuals can voluntarily deploy their attention, allowing them to regulate their more reactive tendencies (Gartstein et al., 2013; Rothbart 2003). In situations where immediate approach is not allowed, for example, children can limit their attention to the rewarding properties of a stimulus, thereby resisting temptation and delaying gratification. Similarly, when faced with a threatening stimulus, children can constrain their fear by attending to environmental sources of safety as well as threat. In both of these examples, individual differences in attention allow children to suppress their more reactive tendencies, take in additional sources of information, and plan more efficient strategies for coping. These capacities have been referred to as effortful control, and they refer to temperamental characteristics that are distinct from extraversion/surgency and the negative emotions. Research indicates some stability of individual differences in effortful control during childhood. For example, the number of seconds delayed by preschool children while waiting for rewards that are physically present has predicted children's parent-reported attentiveness and ability to concentrate as adolescents.

In older children and adults, temperament is often studied through self-reports, allowing analysis of internally experienced feelings as well as behavior. The self-report method is also frequently used in the study of adult personality. In adult research, highly differentiated scales assessing temperament have been factor analyzed, yielding factors very similar to those found in Big Five or Five Factor Model research on adult personality. The Big Five personality factors have been derived from research using trait-descriptive adjectives, following the hypothesis that significant individual differences will be represented in the lexicon, that is, in the words people use to describe others and themselves. The Five Factor Model emerged from factor analyses of large numbers of personality self-report items. There is now considerable agreement for five broad factors of personality derived from this method, including extraverversion, agreeableness, conscientiousness, neuroticism, and openness to experience.

In research using adults' self-reports to scales assessing temperamental reactivity and self-regulation, three resulting factors are similar to those found in children and to measures of the Big Five personality factors. These include temperamental surgency or extraversion, positively related to personality extraversion; negative affectivity, related to neuroticism; and effortful control, related to conscientiousness. In addition, self-reported temperamental orienting to external and internal stimuli is related to personality openness to experience, and temperamental affiliativeness to personality agreeableness. Thus, the structures emerging from temperament research – using basic psychological processes of affect, arousal, and attention – and from personality research – using a lexical or personality-scale analysis – are closely related. Because temperamental individual differences are based upon fundamental psychological and neural processes and are present early in life, these findings suggest that early temperamental predispositions may form a core around which the later-developing personality will be built.

As noted above, temperamental systems are evolutionarily conserved. It is interesting that recent research has attempted to apply 'personality' constructs to studies of nonhuman species. A review of factors identified in studies of twelve nonhuman species has found support for factors of extraversion, including energy and enthusiasm; neuroticism, including negative affectivity and nervousness; agreeableness, including altruism and affection; and openness, including originality and open-mindedness (Gosling and Vazire, 2002). These are seen in the chimpanzee, monkey, hyena, dog, and cat. Several species tested did not give evidence of attentional openness, and evidence for individual differences in conscientiousness was reported only in chimpanzees. It seems likely that these studies, although labeled studies of personality, are getting at the evolutionarily conserved temperamental systems studied in human temperament research. In addition, since not all capacities appear to be shared across species, especially conscientiousness or effortful control, we can recognize important phylogenetic *differences* in temperament. For example, the capacity for effortful control, when linked with language, provides opportunities for self-regulation of reactive systems in humans that are not present in other species.

Advances in neuroscientific imaging technology and in our knowledge of brain networks underlying the emotions and attention have been an additional source of information for students of temperament and development. There is now detailed knowledge of networks subserving fear as well as both reactive orienting and effortful attention (Rothbart et al., 2000). Because imaging studies allow researchers to identify tasks that activate these brain networks, it is possible to adapt these tasks to children of different ages in order to study the development of a temperamental system (Rothbart, 2003). This marker-task approach has been used in the study of the development of attentional orienting and effortful control, but it is likely that marker tasks can be used to assess many additional individual differences. In late twentieth-century research, marker tasks of effortful attention in the laboratory were positively related to parents' reports about children's ability to control attention and emotion.

Methodological Issues or Problems

The usual issues and concerns about psychological measurement apply to the study of temperament. Because the focus of study in temperament is individual differences, it is important to design measures that will demonstrate variability. It is also important that the tests are reliable, giving consistent measurement, and valid, reflecting something meaningful about the child's dispositions. The latter is often demonstrated in a psychological measure's convergence with other measures.

In temperament research, researchers have often been skeptical about using parents as informants about their children's behavior. It has been felt that parental biases or lack of

knowledge will yield measures that are invalid, with direct observation seen as a preferable method. However, considerable evidence indicates convergence between parent report and observational measures (Rothbart et al., 2000). In addition, laboratory observations have their own limitations. For example, it is difficult to collect extensive information about children's emotionality in the laboratory when one emotional experience has carryover effects on another. Fearful children may also behave differently in a strange laboratory situation than less fearful children, because expressions of temperamental dimensions are not independent of one another.

Probable Future Directions of Theory and Research

Temperament is a basic integrative construct within psychology, and improvements in temperament concepts and methods will be critical to advances in understanding development. One goal will be a thorough understanding of the basic processes of temperament, including the components of positive affect/approach, fear, frustration, affiliation, and attention, and how they develop. Understanding the affects and attention will benefit the understanding of temperament, just as temperament analyses will benefit our understanding of the affects and attention. Many advances will come from areas of affective and cognitive neuroscience, where much progress has been made in understanding the emotions and attention. Progress in the study of brain structure and its relation to molecular genetics will also be of great importance.

At the same time, improved assessment methods are needed at multiple levels: measures of behavior in the laboratory, including marker tasks for the development of brain structures, behavior in naturalistic daily contexts, physiological measures, informant reports, and self-reports. Increased use of the laboratory, using marker tasks, brain imaging, and recording, is likely to provide further links with underlying neural systems. Questionnaire measures involving self-report will continue to be important.

To further understanding, it will also be necessary to continue to develop the theory of temperament and its development. Because temperament encompasses organized systems of emotional and attentional processes, rather than separate traits, studies of relationships among temperament variables allow a much richer view of development. In this approach, continuity and change within systems, as well as developmentally changing links among the systems, must be considered. Studies of developmental pathways between early temperament and later personality outcomes will be complex, because childhood and adult individuality unfolds in the context of social relationships, and continuity and change cannot be understood without considering the developmentally changing impact of social experience. To understand developmental pathways, it will be necessary to disentangle complex interaction effects among early temperament predispositions, socialization processes, relationships, and culture.

Because of those complexities, temperamentally different children may arrive at similar or equivalent outcomes via different pathways. Pathways of temperamentally different children may converge over development. For example, Kochanska (2002) has found that fearful toddlers whose parents used gentle discipline, and fearless toddlers whose parents capitalized on positive motivation in a close relationship, attained comparable levels of conscience. Temperamentally similar children's developmental pathways may also diverge as a result of different experiences within relationships or varying cultures.

We have entered a very exciting era in developmental psychology. With support from flourishing neuroscience, genetics, developmental psychopathology, and behavioral research in development, the twenty-first century promises to offer new understanding of the uniqueness of pathways of individual growth. Temperament research will make major contributions to this understanding.

Abstract

Both temperament and motivation have significant outcomes in somatic, societal, and mental well-being. The relationship between temperament and motivation is a two-level phenomenon; genetic/neurobiological and environmental/developmental. Both temperament and motivation are, in part, seen to develop from the reactivity of underlying neurobiological systems, which influence individual differences in attentional, motivational, and self-regulatory functions further. As a result of these core influences, individuals with different temperaments will be exposed to and become motivated by different types of information and environmental stimulation, leading to different content within their 'motivational and developmental representations' as defined by Derryberry and Rothbart.

The Concept of Temperament

There are several temperament theories and models that might differ even in the most essential points of view and define the characteristics of this concept differently. All prevalent and distinguished theories (for a review, see Strelau, 1998), however, agree that temperament refers to a biologically based innate behavioral style, which becomes evident in early childhood and is relatively stable across different situations and over the course of time. The nature of temperament and its differences from ability and motivation have been clarified by defining the temperament as the 'how of behavior,' while ability refers to the 'what and how well of behavior' and motivation reflects the 'why of behavior' (Thomas and Chess, 1977, p. 9).

Although disagreements exist, temperament is usually seen to be relatively independent of cognitions (Oliver et al., 2007). Only low to moderate correlations between traditional measures of IQ and temperament have been found (for reviews, see Guerin et al., 2003; Kristal, 2005), or IQ has been shown to moderate the relation between temperament and academic achievement (Oliver et al., 2007).

Personality and temperament have also been differentiated by some personality researchers (Allport, 1937; Cloninger, 2004). Then, biologically based temperament has been seen as raw material that forms an emotional basis for the later development of personality, which in turn includes cognitions about self and others as well as social factors like values, attitudes, and coping strategies (Rothbart, 2007).

Origins of Temperament

Genetics Background

Temperament has been demonstrated to have a strong biological basis. Although environmental factors, such as culture and education, for example, have significant influence in the manifestation of temperament traits, twin, family, and adoption studies have shown that approximately 50–65% of the variation between individual differences in temperament and personality is due to genetic variation (Gillespie et al., 2003). Research on molecular genetics of temperament traits was initiated in late 1990 by the findings of Ebstein et al. (1996) and Noble et al. (1998), who both revealed an association between Novelty Seeking and Dopamine receptor D4 (DRD4) polymorphism.

Novelty Seeking is one of four temperament traits of Cloninger's Psychobiological Model of Temperament and Character (Cloninger et al., 1993). Other traits of this theory are Reward Dependence, Harm Avoidance, and Persistence. Novelty Seeking is a tendency toward exploratory activity, impulsive decisions, and intense excitability in response to novel stimuli. Harm Avoidance refers to a tendency to inhibit behavior and avoid punishment and novelty, while Reward Dependence is a tendency to respond intensely to social rewards and to learn to maintain rewarded behavior. Persistence is a tendency toward perseverance of behavior despite frustration and exhaustion. These traits predispose a person to specific stimuli (Novelty Seeking to danger, Harm Avoidance to punishment, and Reward Dependence to social reward) and certain emotional reaction when faced with those stimuli. Most important in the context of biological basis of temperament, these traits are suggested to be associated with a biased secretion of specific neurotransmitters, Novelty Seeking with Dopamine, Harm Avoidance with Serotonin, and Reward Dependence with Norepinephrine (Cloninger et al., 1993).

In line with the theory and previous studies, associations of Novelty Seeking with DRD4 (Becker et al., 2005; Dan et al., 2004) and with Dopamine D2 receptor (DRD2) (Comings et al., 1993; Noble et al., 1998) have been supported in later studies while null findings also exist (e.g., Kluger et al., 2002; Light et al., 2007; Szekely et al., 2004). Evidence on associations of Harm Avoidance with Serotonin and Reward Dependence with Norepinephrine have been more conflicting (Becker et al., 2007; Sen et al., 2004). An association of Harm Avoidance with Serotonin transporter 5-HTTLPR, however, has been convincingly demonstrated (Van Gestel et al., 2002). Further, it has been shown that Harm Avoidance by the T102C Serotonin receptor 2A (HTR2A) gene interaction contributes to many adverse developmental paths (Jokela et al., 2007).

In addition to the links suggested by Cloninger's theory, other genetic associations have been found. Harm Avoidance,

for instance, has been shown to be associated with higher μ-opioid receptor availability in regions involved in the regulation of anxiety as well as in the control of emotions (Tuominen et al., 2012). Further, the interaction between catechol-*O*-methyltransferase (COMT) and Serotonin receptor 2A, in turn, might contribute to Novelty Seeking (Salo et al., 2010).

Until now, the findings on molecular genetics have not been consistent enough to definitely associate temperament to its suggested neurobiological origins, but rather, they are likely to generally refer to a neurobiological basis of temperament, and suggest that further research is needed. In addition, single gene associations are no more in the current interest of research, but instead, gene families and interactions of several genes are focused on.

Environmental Factors

The direct associations of various childhood environmental factors (such as parental depressive symptoms, hostile child-rearing attitudes, insecure attachment style, and alcohol intake) with the phenotype of temperament have been convincingly shown (e.g., Pesonen et al., 2004). Although direct environmental and genetics effects on the development of temperament have been demonstrated, the recent research has increasingly focused on interactions, that is, in gene-by-environment interactions predicting the development of temperament, and in temperament-by-environment interactions predicting the development of personality or adulthood societal and health outcomes of temperament.

Interactions between environmental and genetic factors predicting Novelty Seeking have been recently demonstrated in many studies, for example, by Keltikangas-Järvinen et al. (2009). They have shown that after 21 years of follow-up, the participants carrying any A1 allele of the DRD2 gene scored higher on Novelty Seeking than carriers of the A2/A2 genotype, when the childhood environment was strict and punitive. However, when the childhood environment was more encouraging, no genotype effect was found. Furthermore, the presence of the A/A haplotype of the TPH1 intron 7 A218A and A779C genes has predicted higher Harm Avoidance in adulthood when the childhood environment has been hostile (i.e., emotional rejection, maternal neglect, and harsh and inconsistent discipline) (Keltikangas-Järvinen et al., 2007).

Childhood temperament and environment may have direct or interactive effects on health. Anger of the child, for example, has been related to increased systolic blood pressure and high levels of high-density lipoprotein cholesterol (HDL-C) in serum (Ravaja et al., 2001). Childhood temperament and maternal child-rearing attitudes, in turn, have been found to contribute to the early development of insulin resistance syndrome (IRS) in a gender-specific way among children, thereby potentially increasing the risk of coronary heart disease later in life. Among boys, 'difficult temperament' (i.e., anger, activity, and low cooperativeness) increased the risk of having IRS risk-factor clustering, and hostile maternal child-rearing attitudes predicted increased HDL-C. Among girls, there were no significant cross-lagged effects between the behavioral factors and IRS, but child's low emotional significance to the mother increased the risk of IRS in the child (Ravaja et al., 2001).

Regarding a childhood temperament-by-environment interaction, a number of longitudinal studies have demonstrated a close interplay between the child's own, partly genetically determined temperament and environmental factors related to mothering, such as maternal role satisfaction, in the development of self-esteem and depressive tendencies in youth, and dispositional optimism–pessimism in adulthood (e.g., Heinonen et al., 2003).

Significance of Temperament in Academic Achievement

Student temperament has been shown to be a significant factor in studying situations and academic settings. For example, it plays a role in students' social functioning and peer relations in school environment (Hintsanen et al., 2010) and is associated with unemployment in young adults (Hintsanen et al., 2009). In daily classroom life, student temperament is associated with teacher–student interactions (e.g., Rudasill and Rimm-Kaufman, 2009), teacher expectations (e.g., Stipek, 2002), and teacher's educational decisions concerning a student (Rothbart and Jones, 1998). Consequently, temperament has been shown to predict academic achievement evaluated by both standardized achievement tests and teacher-assigned school grades (Guerin et al., 2003). In a series of recently published studies in a population-based sample of Finnish upper-comprehensive schools (e.g., Hintsanen et al., 2012; Mullola et al., 2014), approximately a proportion of one-third of teacher-assigned school grades in mathematics and mother language were explained by student's teacher-perceived temperament. The associations and their effect sizes were in line with the previous literature (for a review, see Guerin et al., 2003) and the given boundary values (Cohen, 1988), and thus suggested moderate to rather strong associations between student temperament and school grades (Mullola et al., 2014).

There are at least five mechanisms through which temperament may be associated with academic achievement. First, temperament may be mediated through an individual's natural working style (for a review, see Kristal, 2005), chosen problem-solving strategies (Davis and Carr, 2002), interests (Elliot and Thrash, 2002; Guerin et al., 2003), and willingness to approach learning tasks, especially the novel ones (Caspi and Shiner, 2006). Activity (i.e., tendency to show frequent and intense motor vigor and tempo), persistence (i.e., long attention span and a tendency to continue seeking a solution to difficult learning or performance problems), and distractibility (i.e., the ease with which a student's attention can be interrupted by low-level environmental stimuli) form a constellation called temperamental task orientation, which affects a student's attention span and tolerance to frustration when learning new skills as well as the ability to complete academic activities (e.g., homework) (Martin and Bridger, 1999). Therefore, high task orientation (i.e., low activity, high persistence, and low distractibility), might, for example, enable the student to have more assisting tools for self-regulating his/her learning process and for enhancing opportunities for the successful accomplishment of school tasks (for reviews, see Guerin et al., 2003; Kristal, 2005). On the contrary, the student with low task orientation (i.e., high activity, low persistence, and high

distractibility) is easily 'sidetracked' from the given learning task, particularly from a difficult one. It is challenging for him/her to maintain attention and to be seated still throughout long periods of time, which requires high concentration and involves occasions of frustration (Martin and Bridger, 1999).

The second mechanism that links temperament and academic achievement is that teachers experience certain temperament traits as more 'teachable' (i.e., a teacher's perception of the temperamental attributes of an ideal student) than other traits, reflecting the 'school appropriate behavior' (i.e., follows directions, is attentive and alert to classroom events, and finishes tasks on time) (for a review, see Keogh, 2003). This further affects teachers' teaching practices and grade giving toward the given student, which may even lead to the so-called 'self-fulfilling prophecies' (Jussim and Harber, 2005). In addition to task orientation mentioned above, other factors of teachability are personal–social flexibility (i.e., the combination of approach–withdrawal/inhibition, adaptability, and level of positive mood) and reactivity (i.e., the combination of threshold of response (which is the intensity and strength of the stimulation that is needed to arouse a reaction), level of negative mood, and intensity of response (which is the expressive and reactive energy of a reaction, whether happy, sad, or angry) (Keogh, 2003; Kristal, 2005). Personal–social flexibility contributes to how fluently changes and transitions go during the school day. Reactivity, in turn, contributes to teachers' opinions of a student (e.g., how much a teacher likes a student), and is also associated with a teacher's perception of a student's personal–social competencies (for a review, see Keogh, 2003) and social position in the class (Hintsanen et al., 2010).

Students with low task orientation, low personal–social flexibility, and high reactivity are consistently perceived by their teachers as less teachable and as having poor educational competence (i.e., teacher-perceived student cognitive ability, motivation, and maturity) (Keogh, 2003; Mullola et al., 2010). Teachers have been found to underestimate the intelligence, motivation, maturity, and cognitive ability of students with low teachability compared with the results of standardized cognitive tests (for a review, see Keogh, 2003). Student's lower teacher-perceived learning style and teachability (i.e., lower 'how of behavior' as defined by Thomas and Chess, 1977, p. 9) are seen as less 'school appropriate behavior.' Further, these students are perceived by their teachers as less motivated (i.e., lower 'why of behavior'), less capable, and less mature. Instead, students with high teacher-perceived teachability (i.e., high task orientation, high personal–social flexibility, and low reactivity) are experienced positively by teachers regarding their learning style. Consequently, they are perceived as more motivated, mature, and capable as well beyond their actual age and performance (Martin and Bridger, 1999).

Third, the association between student temperament and academic achievement may be mediated through teacher-perceived teachability. As teacher-rated temperament seems to be more strongly associated with school grades than students' self-rated temperament (Hintsanen et al., 2012), it is possible that the grade giving may be biased by teachers' perceptions of student temperament (the so-called 'halo-effect'). Low task orientation, in particular, correlates with lower grade point averages (Ham et al., 2006) and lower teacher-rated school grades (Mullola et al., 2010), even when students' self-rated temperament (Mullola et al., 2014), and cognitive ability and motivation (Hintsanen et al., 2012) have been controlled for during the analyses. Student's teacher-perceived high personal–social flexibility (positive mood and high adaptability), in particular, have been shown to predict higher grades than might be expected on the basis of standardized achievement tests (for a review, see Keogh, 2003). Teachers' ratings of student teachability and school grades may also vary by their gender, age, and by student gender (Mullola et al., 2011, 2012). Additional research is, however, needed in order to get more information about the possible bias in grade giving. It is also essential to examine the associations of teacher- and self-rated temperament traits with objective test results and to compare these associations with associations with the grades given by teachers.

The forth mechanism that links temperament and academic achievement is the possibility that the 'halo effect' runs in the opposite direction. This means that temperaments of gifted or high-ability students are evaluated more positively. Therefore, in future studies it is important to control students' standardized cognitive ability test performances during the analyses.

The Significance of Motivation in Education and Well-Being

Motivation is one of the most significant factors in educational and occupational settings (Hazrati-Viari et al., 2012; Komarraju et al., 2009; Tanaka et al., 2009) and also in general well-being related to important life goals, such as personal growth, relationships, community, health, and wealth (Gomez et al., 2012; Lüdtke et al., 2009). Salmela-Aro and colleagues have prospectively examined the effects of different goal contents (i.e., family-focused or self-focused) on subjective well-being in different age groups and life transitions (Salmela-Aro and Nurmi, 1997; Salmela-Aro et al., 2001; Salmela-Aro et al., 2009). The level of mother-perceived depressive symptoms during and after pregnancy, for example, has been predicted by family- and self-focused personal goals (Salmela-Aro et al., 2001). Subjective well-being in young adulthood have been predicted by an individual's interest in family-related goals, whereas low self-esteem have been predicted by interest in self-related goals and by low subjective well-being, further (Salmela-Aro and Nurmi, 1997). In another recent study, the importance of intrinsic goals has functioned as a mediator between extraversion and subjective well-being particularly in older adults, which also indicates some age-specificity in the dynamic interaction of temperament and motivation with general well-being (Gomez et al., 2012).

Research has shown that highly motivated individuals are more alert to their learning processes and outcomes (Bouffard-Bouchard et al., 1991), choose more challenging tasks (Chang and Burns, 2005; Zimmerman and Schunk, 2009), and set more energy and persistence to learn demanding tasks on their own when trying to achieve higher levels of skills and positions (Schunk and Hanson, 1985) than poorly motivated individuals. Further, individuals who are highly motivated experience deeper satisfaction and more positive affect than poorly

motivated individuals when given the occasion to learn and advance (Zimmerman and Kitsantas, 1999). Consequently, these aspects enhance an individuals' satisfaction in educational and occupational circumstances, which is widely demonstrated to be associated with various forms of general well-being and subjective gratification in life (Gomez et al., 2012; Lüdtke et al., 2009).

The Interaction between Temperament and Motivation

Previous literature nominates at least four central temperament and personality theories, whose concepts are suggested to be associated with each other and with motivation. These theories are (1) Five Factor theory (McCrae and Costa, 2003); (2) the Psychobiological Model of Temperament and Character (Cloninger et al., 1993); (3) The psychophysiological basis of introversion–extraversion (Gray, 1970); and (4) Reactive and effortful processes in the organization of temperament (Derryberry and Rothbart, 1997). The interactive biological processes between temperament and motivation influence behavioral functions, which manifest particularly in educational and occupational environment and also in subjective well-being. In most theories, temperament is suggested to be heritable, observable in early childhood, relatively stable across the life span and predictive of adolescent and adult unique behavior (Cloninger et al., 1993; Elliot and Thrash, 2002; Eysenck and Eysenck, 1987; Gray, 1982; McCrae and Costa, 2003). The above-mentioned four theories all contain an affective element, and the conceptualizers of the theories have used the term temperament to describe the nature of their structures (Cloninger et al., 1993; Elliot and Thrash, 2002; Eysenck and Eysenck, 1987; Gray, 1982; McCrae and Costa, 2003). Some of those theories make a distinct difference between temperament and personality, while others emphasize their overlapping and developmental paths between them. In the following text, a clear difference has not been made.
